INTRODUCTION

The Government of Madras took up for consideration the question of publication of the various manuscripts in different languages on subjects like Philosophy, Medicine, Science, etc., early in May 1948. Important Manuscripts Libraries in the Madras Presidency were requested to send lists of unpublished manuscripts with them for favour of being considered by the Government for publication. The Honorary Secretary of the Tanjore Maharaja Serfoji's Saraswati Mahal Library, Tanjore, alone complied with this request. This list as well as a similar list of unpublished manuscripts in the Government Oriental Manuscripts Library, Madras, were carefully examined and a tentative selection of manuscripts suitable for publication was made. The Government in their Memorandum No. 34913/48-10, Education, dated 4th April 1949, constituted an Expert Committee with the Curator of the Government Oriental Manuscripts Library, Madras, as the Secretary, for the final selection of manuscripts suitable for printing and for estimating the cost of publication.

The following were the members of the Committee :—

1. Sri T. M. Narayanaswami Pillai, M.A., B.L.
2. Sri R. P. Sethu Pillai, B.A., B.L.
3. Sri C. M. Ramachandran Chettiar, B.A., B.L.
4. Sri R. Krishnamurthi, (Kalki).
5. Dr. N. Venkataramanayya, M.A., Ph. D.
6. Sri M. Ramanuja Rao Naidu, M.A.
7. Sri V. Prabhakara Sastri.
8. Sri N. Venkata Rao, M.A.
9. Sri H. Sesha Iyengar.
10. Sri Masti Venkatesa Iyengar.
11. Sri M. Mariappa Bhat, M.A., L.T.
12. Dr. C. Achyuta Menon, B.A., Ph. D.
13. Dr. C. Kunhan Raja, M.A., D. Phil.
14. Dr. A. Sankaran, M.A., Ph. D., L.T.
15. Sri Polakam Rama Sastri.
16. Sri S. K. Ramanatha Sastri.

17. Dr. M. Abdul Huq, M.A., D. Phil. (Oxon).
18. Sri Afzul-Ul-Ulma Hakim Khadar Ahamad.
19. Sri P. D. Joshi.
20. Sri S. Gopalan, B.A., B.L.
21. Sri T. Chandrasekharan, M.A., L.T., Curator.

With the exception of Sri Masti Venkatesha Iyengar and Dr. C. Kunhan Raja, the above members continued to be members of the Expert Committee for 1950-51 also to which the following gentlemen were added in Government Memos. No. 7297-E/50-3, Education, dated 19th May 1950, and 15875-E/50-4, Education, dated 7th September 1950:—

1. Dr. A. Chidambaranatha Chettiar, M.A., Ph. D.
2. Sri S. Govindarajulu Naidu, B. A., B. L., LL. B., Bar-at-Law.
3. Capt. G. Srinivasamurti, B.A., B.L., M. B. & C.M.
4. Dr. Muhammad Hussain Nainar, M.A., Ph. D.
5. Sri T. V. Subba Rao, B.A., B.L.
6. Principal, College of Indigenous Medicine, Madras.

In Government Memorandum No. 18947-E/52-2, Education, dated 7th August 1952, a few changes were made in the personnel of the Expert Committee.

The names of the following members were deleted :—

1. Sri V. Prabhakara Sastri.
2. Dr. C. Achyuta Menon.
3. Dr. M. Abdul Huq.

The following gentlemen were included as members of the Expert Committee :—

1. Sri M. Somasekhara Sarma.
2. Dr. V. Raghavan, M.A., Ph. D.
3. Dr. R. Nagaraja Sarma, M.A., Ph. D.
4. Dr. S. Krishnan Nayar, M.A., Ph. D.
5. Prof. S. A. Bukhari, M.A.

In G. O. Ms. No. 1819 Edn., dated 8-11-1955, the Government reconstituted the Expert Committee with the

following members :—

SANSKRIT

1. Dr. A. Sankaran, M.A., Ph. D., L.T.
2. Sri P. S. Rama Sastri.
3. Dr. V. Raghavan, M.A., Ph. D.
4. Dr. R. Nagaraja Sarma, M.A., Ph. D., L.T.
5. Sri K. Balasubrahmanya Iyer, B.A., B.L., M.L.C.

TAMIL

6. Sri T. M. Narayanaswami Pillai, M.A., B.L., M.L.C.
7. Sri R. P. Sethu Pillai, B.A., B.L.
8. Sri C. M. Ramachandran Chettiar, B.A., B.L.
9. Sri T. P. Meenakshisundaram Pillai, M.A., M.O.L.
10. Dr. A. Chidambaranatha Chettiar, M.A., Ph. D.
11. Sri N. T. Viswanathan, B.A., B.L.

KANNADA

12. Capt. G. Srinivasamurti, B.A., B.L., M.B. & C.M.
13. Sri M. Mariappa Bhat, M.A., L.T.
14. Sri H. Sesha Iyengar.

MALAYALAM

15. Dr. S. Krishna Nayar, M.A., Ph. D.

MARATHI

16. Sri P. D. Joshi.

ISLAMIC LANGUAGES

17. Prof. S. A. W. Bukhari Sahib, M.A., L.T.
18. Dr. Mohammad Abdul Huq, M.A., D. Phil. (Oxon).
19. Sri S. M. Fazullah, M.A., L.T.

OTHERS

20. Sri S. K. Ramanatha Sastri, Sanskrit and Malayalam.
21. Sri T. V. Subba Rao, B.A., B.L., Music in all languages.

22. The Principal, College of Indigenous Medicine, Madras, Medicine in all languages.

23. Sri S. Gopalan, B.A., B.L., Sanskrit, Tamil and Telugu.

24. Sri T. Chandrashekharan, M.A., L.T., In all languages (Secretary of all the Committees).

The members of the Committee met in Madras and Tanjore to examine the manuscripts and make a selection. The recommendations of the Committee were accepted by the Government and they decided to call these publications as the "MADRAS GOVERNMENT ORIENTAL SERIES" and appointed the Curator, Government Oriental Manuscripts Library, Madras, as the General Editor of the publications under this series.

The following manuscripts were taken up for publication till now :—

"A" FROM THE GOVERNMENT ORIENTAL MANUSCRIPTS LIBRARY, MADRAS.

TAMIL

1. Kappal Śāttiram.
2. Anubhava Vaiddiya Muṛai, Vols. I & II.
3. Āttānakōlāhalam.
4. Upadēśa Kāṅdam.
5. Colan Pūrva Paṭṭayam.
6. Śivajñāna Dīpam.
7. Daṭchanāyanār Vaiddiya Aṭṭavaṇai.
8. Vaiddiya-k-Kalañciyam.
9. Anubhava Vaiddiya Muṛai, Vol. III.
10. Saptarṣināḍi, Vol. I—Mēṣa Lagnam.
11. Karṇāṭakarājākkal Savistāra Charittiram.
12. Bharata Siddhāntam.
13. Pillai-p-piṇivākaṭam, Vol. I.
14. Anubhava Vaiddiya Muṛai, Vol. IV.
15. Māṭṭuvākaṭam.
16. Saptarṣināḍi, Vol. II—Viruṣabha Lagnam

17. Temple Inscriptions of South India, Vol. I.
18. Saptarṣināḍi, Vol. III—Mithuna Lagnam.
19. Temple Inscriptions of South India, Vol. II.
20. Pillai-p-piṇi vākaṭam (on infantile diseases), Vol. II
21. Saptarṣināḍi, Vol. IV—Kaṭaka Lagnam.
22. Pērūr-k-Kōvai.
23. Siddhāntavilakkam.
24. Sāmudrikālakṣaṇam.
25. Ānandaraṅga-k-Kōvai.
26. South Indian Temple Inscriptions, Vol. III, Part I.
27. Saptarṣināḍi, Vol. V—Simha Lagnam.
28. Maghasnānapurāṇa Ammānai.
29. Kōlācala Sthala Purāṇam.
30. Dina Kavitai.
31. South Indian Temple Inscriptions, Vol. III, Part II.

10. Saṅgītadarpaṇa.

The Government in their G. O. Ms. No. 1820, Education. dated 4th August 1952, sanctioned a grant of Rs. 9,000 to the Dr. V. Swaminatha Aiyar's Tamil Library, Adyar, towards the publication of the following manuscripts as part of the "Madras Government Oriental Series":—

1. Tiruvāchaka-vyākhyānam.
2. Mahābhārata Chūḍāmaṇi.

It is hoped that the publication of most of the important manuscripts will be completed within the next few years.

Some of the manuscripts taken up for publication are represented by single copies in the library and consequently the mistakes that are found in them could not be corrected by comparing them with other copies. The editors have, however, tried their best to suggest correct readings. The wrong readings are given in round brackets. When different readings are found, they have been given in the foot-notes except in the case of a few books in which the correct readings have been given in the foot-note or incorporated in the text itself.

The Government of Madras have to be thanked for financing the entire scheme of publication although there is a drive for economy in all the departments. My thanks are due to the

members of the Expert Committee who spared no pains in selecting the manuscripts for publication. I have also to thank the various editors, who are experts in their own field, for readily consenting to edit the manuscripts and see them through the press. The various presses that have co-operated in printing the manuscripts in the best manner possible also deserve my thanks for the patience exhibited by them in carrying out the corrections made in the proofs.

The Mahābhāskarīya presented here in a critical edition is a work on astronomy, important not only due to its being an early work (c. 600 A. D.), but due to its elaboration of the Āryabhaṭan school of Indian astronomy. The Bhāṣya of Govindasvāmin (c. 800) and the detailed sub-commentary Siddhāntadīpikā by Parameśvara (c. 1365-1460) are also significant contributions on the subject. Sri T. S. Kuppanna Sastri, the Editor, has prefixed this edition with a critical study on these three works besides a Summary of Contents setting out the main argument of the Mahābhāskarīya. He has also added several indices to the edition to facilitate easy reference to the book.

The text of the Mahābhāskarīya is edited here on the basis of eight manuscripts, two of which are from this Library, Nos. R. 5138 and D. 13465. Of the five manuscripts used for determining the reading of the Bhāṣya, one, No. R. 5138, belongs to this Library. The other manuscripts of the text and the Bhāṣya, as also the two manuscripts of the sub-commentary Siddhāntadīpikā are from the Travancore University Manuscripts Library and H. H. The Maharaja's Palace Library, Trivandram, to which institutions I take this occasion to express my thanks for their co-operation in the present edition. For a detailed study of the manuscripts, their mutual relationship and peculiarities, and a discussion of the variants, I invite the attention of the readers to the Editor's Introduction below.

1st January, 1957. }　　　*T. Chanadrasekharan*

INTRODUCTION

The author and his works

The *Mahābhāskarīya* edited here critically with its *Bhāṣya* and a super-commentary thereon is an important work in Indian astronomy written by Bhāskara I (*c.* 600 A. D.) who must be distinguished from the later and wellknown Bhāskarācārya II, author of *Līlāvatī*, *Bījagaṇita* and the *Siddhāntaśiromaṇi* (1150 A. D.). So far as we know our Bhāskara has written three works, the *Mahābhāskarīya*, the *Laghubhāskarīya* and a *Bhāṣya* on the *Āryabhaṭīya*. He seems to have intended the *Mahābhāskarīya* as an exposition on the *Āryabhaṭīya*, as well as an independent work. The *Laghubhāskarīya* is an epitome of the *Mahābhāskarīya*.

The real name of Mahābhāskarīya

Though popularly known by the names *Mahā-Bhāskarīya* and *Bṛhad-Bhāskarīya*, the name intended by the author to the work is *Karmanibandha*, 'a treatise on astronomical calculations'. In his *Āryabhaṭīya-Bhāṣya* (*ABh.Bhāṣya*) Bhāskara often refers to this work using the words: उक्तं च अस्माभिः कर्मनिबन्धे and quotes from it. In the present work too he indicates the name in two places: निबन्धः कर्मणां प्रोक्तो (VIII. 21) and सम्यगार्यभटकर्मनिबन्धः (VIII. 24). Govindasvāmin, the commentator of the work, too refers to it only by this name in his introductory verse: व्यक्तेनोक्तो निबन्धः पृथुतरगणितं कर्मणां भास्करेण। Sometimes the work is called *Bṛhat-Karmanibandha* to distinguish it from the *Laghu-Karmanibandha* used with reference to the third work of Bhāskara, the *Laghu-Bhāskarīya*[1].

Identity of the author

Little is known about Bhāskara's place of birth, parentage or private life. He seems to have been forgotten after sometime in the North and only recently has he come to be known there

---

1. See Śaṅkaranārāyaṇa in his commentary on the *Laghubhāskarīya*, VIII.19, Trivandrum Sanskrit Series, No. 162.

again[1]. MM. Sudhakara Dvivedi's *Gaṇaka Taraṅgiṇī* does not contain any account of this Bhāskara. S. B. Dikshit too does not make any mention of him in his *History of Hindu Astronomy*. If these did not know him we can take it that few others knew of him. H. Colebrooke, however, guessed as early as 1817 the existence of an earlier Bhāskara through certain references by Pṛthūdakasvāmin in his commentary on the *Brahmasphuṭa Siddhānta*, though, of course, he could not identify him.[2]

In the South, on the other hand, Bhāskara I and his works have been well-known amongst astronomers. The *Vākyakaraṇa*, or *Vākya-pañcādhyāyī* as it is otherwise called, on which the Tamilnad *Vākya Pañcāṅgas* are based, purports to follow the *Bhāskarīya* as can be gathered from statements in that work like: भास्करीयानुसारेण गणितं क्रियते लघु। (I. 1), तद्दिनान्मध्यशीघ्रोच्चं ज्ञेयं भास्करतन्त्रतः। (II. 20). In Kerala he has always been widely known amongst astronomers as the interpreter of Āryabhaṭa and next only to him in importance. It is in Kerala that his works are extant and his commentators like Govindasvāmin, Śaṅkaranārāyaṇa, Parameśvara, and Nārāyaṇa are all astronomers hailing from this part of the country. Commentaries on Bhāskara are available in the Malayalam language too.[3]

Bhāskara's place of birth

As for the place where Bhāskara hailed from, we do not have sufficient evidence to say anything definitely. In his *ABh.Bhāṣya* on the *Gaṇitapāda*, while giving examples in problems of Time and Distance,

---

1. Specific attention to this author was first drawn by B. B. Datta in 1930 in his article, 'The two Bhāskaras', *IHQ* VI. 729-36

2. *Cf. Algebra with Arithmetic and Mensuration, from the Sanskrit of Brahmagupta and Bhāskara*, London, 1817, Introd. p. xl.

3. For three different Malayalam commentaries on the *Laghu-bhāskarīya*, See Travancore Univ. Mss. Lib., Trivandrum, Mss. Nos. T. 286, C. 2146-A, and H. H. The Maharaja's Palace Library, Trivandrum, Ms. No. 946.

(page 127)[1], he takes places like Valabhī, Harukaccha and Śivabhāgapura. He gives the Equinoxial shadow of Sthāneśvara as being 7 *aṅgulas* and of Ujjain as 5 *aṅgulas*. He gives the practice in Saurashtra of beginning of year with *Kārtika Śukla Pratipad*. May these indicate that he belonged to the part of India near Valabhi? It is also not known how he came to be connected with the Kerala country and the Āryabhaṭan school of astronomy. Other personal details known about Bhāskara are that he was a devotee of Śiva to whom he pays obeisance in his *Mahābhāskarīya* and his *Āryabhaṭīya-bhāṣya*[2], and that he imbibed his knowledge of astronomy from his father, who should also, therefore, have been an astronomer of the school of Āryabhaṭa. Cf. यथा पितुः संप्रदायाविच्छित्तिकथने ग्रहपातेषूक्तं तदत्राप्यवधारणीयमिति । (page 47).

Date of Bhāskara

Bhāskara's date can be fixed more or less definitely from external evidences, though there does not seem to be any specific statement of the fact in his works. Against the view of some scholars[3] that our author was a direct pupil of Āryabhaṭa who wrote the *Āryabhaṭīya* in 499 A.D., and so is a younger contemporary of the latter, there are evidences to show that Bhāskara could not have been a direct pupil of Āryabhaṭa :

(i). In several places in his *Bhāṣya* on the *Āryabhaṭīya*, Bhāskara says that his interpretation of the work is as got from a continuous chain of teachers; cf. संप्रदायाविच्छेदात् , which expression he would not have used if he were a direct pupil. See for instance : कस्यार्धं ऋणं

---

1. The page references to Bhāskara's *Āryabhaṭīya-Bhāṣya* are to its transcript in the Govt. Oriental Mss. Library, Madras, No. R. 14850, prepared from two original palmleaf Mss. in Malayalam script procured from Kerala.

2. *cf*. नमोऽस्तु तस्मै सुरवन्दिताङ्घ्रये समस्तविद्याप्रभवाय शम्भवे ।
(*Mahābhāskarīya* I. 1)
तस्मै सकृष्णकमलोद्भवमौलिपृष्टपादारविन्दयुगलाय नमः शिवाय ॥
(*Āryabhaṭīya-bhāṣya, Gaṇitapāda*)
तस्मै नमस्त्रिभुवनस्थितये शिवाय । (*ibid, Kālakriyāpāda*).

3. See below.

धनं वा भवतीत्यत्र संप्रदायाविच्छेदात् मन्दसिद्धमध्यान्तरं परिगृह्यते । (p. 219); संप्रदायाविच्छेदाद् व्याख्यायते । (p. 129); आचार्येणैव यदाख्यातं तदेवा-विच्छिन्नसंप्रदायप्रतिपत्त्याभिधीयते । (p. 46).

(ii). Again speaking about Āryabhaṭa he says, "This is what we *hear* about this great ācārya: By great penance he got the lore of Astronomy." (*Āryabhaṭīya-bhāṣya, page 19)*, using the words एवमनुश्रूयते । If he had known Āryabhaṭa personally Bhāskara would not have used this expression.

(iii). Bhāskara criticises Prabhākara reputed to be a pupil of Āryabhaṭa[1] and his commentary on the *Āryabhaṭīya* in the following strain: आचार्यप्रभाकरेण........अयमेव विग्रहः प्रदर्शितः । स गुरुरिति कृत्वा अस्माभिर्नोपालभ्यते । (p. 81); इदं च व्याख्यानं आचार्यप्रभाकरेण व्याख्यातम् । तच्चायुक्तं...अनर्थकमप्रत्याख्याय व्याख्यानं कर्तुम् । (p. 90)

These statements naturally presuppose that Bhāskara came later than even Prabhākara, a disciple of Āryabhaṭa.[2]

(iv). Again in his *Bhāṣya* on the *Āryabhaṭīya* commenting on the verse शनि etc. (Kālakriyā, 22b), Bhāskara says, अन्ये पुनरन्यथा पठन्ति—'शनिबुधकुजेषु मन्देऽर्धमृणधनं भवति पूर्वम्' इति । (page 229). Had Bhāskara been a pupil of Āryabhaṭa he could have authoritatively given the correct reading and dismissed the other as incorrect. The fact that he does not do so and gives it only as a variant, would show that he was not a direct pupil of the author of the original.

But in some quarters it is asserted[3] that the date of Bhāskara's *Laghubhāskarīya* is 522 A. D. (*i. e.* 23 years after the composition

---

1. *Cf.* Bhāskarācārya II, in his commentary on Lalla's *Śiṣyadhīvṛddhida, Spaṣṭādhikāra*, 43 : आर्यभटशिष्याः प्रभाकराद्यः ।

2. Incidentally, Bhāskara's mention of Prabhākara shows that they cannot be identical, as asserted by B. B. Datta (The Two Bhāskaras, *IHQ* VI (1930) 732), and Sukumar Ranjan Das (A short chronology of Indian astronomy, *IHQ* VII (1931) 146-47).
3. *Cf.* B. B. Datta, The Two Bhāskaras, *IHQ* VI (1930) 729-30 ; Datta and Singh, *History of Hindu Mathematics*, II. 66.

of the *Āryabhaṭīya*) and therefore he must have been a direct pupil since he is an advocate of the school of Āryabhaṭa coming so closely after Āryabhaṭa. This is obviously due to a confusion created by the following verse found interpolated in a Ms. of *Laghubhāskarīya* after I. 17:

वाग्भावोनाच्छकाब्दाद् धनशतलवहान्मन्दवैलक्ष्यराशैः
प्राप्ताभिर्लिप्तिकाभिर्विरहिततनवश्चन्द्रतत्तुङ्गपाताः ।
शोभानीरूढसंविद्गणकनरहतान्मागराप्ताः कुजाद्याः
संयुक्ता ज्ञारसौरा सुरगुरुभृगुजौ वर्जितौ भानुवर्जम् ॥

Since this verse was taken to belong to *Laghubhāskarīya* the epoch given in it, *viz*. Śaka 444 (represented by **वाग्भाव** according to the *kaṭapayādi* system of notation), was inferred as the date of the work or very near it. But this is known to be really a later verse[1] giving the primary *Bīja* correction of the Parahita system of Kerala astronomy for the mean Moon etc. got by the *Āryabhaṭīya*[2] and has nothing to do with Bhāskara[3]. As for the epoch 444 Śaka (522 A.D.), this is given on the mistaken impression that this is the date of composition of the *Āryabhaṭīya*, and the correction is sought to be given from this date to the mean of the Moon and other planets as calculated from the *Āryabhaṭīya* constants. The mistake is due to some astronomers having interpreted the following verse of Āryabhaṭa:

---

1. But this not from the *Karaṇapaddhati* of Putumana Somayāji as stated in the Introduction, p. x, of the Trivandrum edition of the *Laghubhāskarīya* with Śaṅkaranārāyaṇa's commentary (*TSS* No. 162).

2. Cf. K. V. Sarma, Introduction, p. x, to his edition of the basic manual of the Parahita system of astronomy *Grahacāranibandhana*, Madras, 1953.

3. Two other things may also indicate that this does not belong to the *Laghubhāskarīya*. While *bhūta-saṅkhyā* is used *throughout* the work, this stanza uses the *kaṭapayādi* notation. While the *whole* work is in *Śloka* metre (except two stanzas at the end giving problems in *kuṭṭaka*), the present verse is in a different metre.

षष्ट्यब्दानां षष्टिर्यदा व्यतीतास्त्रयश्च युगपादाः ।
त्र्यधिका विंशतिरब्दास्तदेह मम जन्मनोऽतीताः ॥

(*Āryabhaṭīya*, *Kālakriyā*, 10)

thus: "I was born at the end of Kali 3600; I write this work when I am 23 years old, *i. e.* at the end of Kali 3623" (Śaka 444 or A. D. 522)[1]. The author of the stanza वाग्भाव must have been one such wrong interpreter and the Śaka 444 which he intended as the date of the *Āryabhaṭīya* has been mistaken to be the date of Bhāskara by the above-mentioned historians.[2]

We may consider now what evidence there is to fix Bhāskara's date. From the foregoing discussion we may not be wrong in fixing the upper limit to Bhaskara's date at 550 A. D. The lower limit may be fixed as 628 A. D., the date of Brahmagupta's *Brahmasphuṭasiddhānta* from the following considerations. It is certain that Bhāskara is earlier than his *Bhāṣyakāra*, Govindasvāmin, who is earlier than Śaṅkaranārāyaṇa (869 A. D.) who mentions Govindasvāmin in his salutation at the beginning of his *Laghubhāskarīya-vivaraṇa*), and also than Pṛthūdakasvāmin (860 A. D.) who mentions Bhāskara in several places in his commentary on the *Brahmasphuṭasiddhānta*. Pṛthūdaka makes statements implying that Bhāskara's works must have been known to Brahmagupta. In defending Āryabhaṭa from Brahmagupta's attack in his work, Pṛthūdaka tries to turn the attack from Āryabhaṭa and make Bhāskara the target: *cf.* 'The attack on Āryabhaṭa's *sūtras* made on the basis of Bhāskara's interpretation would be proper only if Bhāskara has given the correct

---

1. The Kerala astronomer Nilakaṇṭha Somayāji in his *Āryabhaṭīya-bhāṣya* on this verse draws attention to this wrong interpretation and corrects it. *Cf. TSS* 110, pp. 12-18.

2. What is more, on the strength of this stanza they conclude that this is the first instance of the use of the *Kaṭapayādi* notation. It is also strange that the Introduction of the *TSS.* edn. of the *Laghubhāskarīya* which has pointed out that the verse वाग्भावोन does not belong to that text, has given the date of Bhāskara as 522 A. D. on the authority of Datta and Singh who have given this date on the strength of this repudiated stanza.

meaning of the *sūtras*' —सद्दूषणमेतदार्यभटसूत्रस्य यदि नाम भास्करेणोपाख्यानं कृतं स्यादार्यभटहृदयानुसारीति । (Com. on *Br. Sph. Sid.* XI. 22); again, 'Therefore this is not Āryabhaṭa's fault. It may be the fault of Bhāskara and others; they have not understood him properly'—तस्मादार्यभटस्य नायं दोषः । भास्करादीनामेव भवतु । तैर्न बुद्धस्तदभिप्रायः । (*ibid.* XI. 26). Whether Pṛthūdaka's defence of Āryabhaṭa is tenable or not, it is certain that he considers Brahmagupta to be criticising Bhāskara and not Āryabhaṭa, thereby showing that according to him Bhāskara is earlier than Brahmagupta, or at least not later. And Pṛthūdaka coming so close after Bhāskara and Brahmagupta, cannot be wrong in this, especially since he is a writer on the same subject of astronomy. We can thus fix the limits of Bhāskara's date between 550 and 628 A. D.[1] To attempt a closer approximation: Bhāskara gives 0^0 longitude to the Junction Star of *Revatī* (*Zeta piscium*) and as he positively thinks the Vernal Equinox to be coincident with the beginning of the Sign Meṣa, we have to take it that his observations place the Vernal Equinox at *Zeta piscium*. Actually it was there in 574 A. D., which agrees with the limits of his date arrived at above.[2]

The school of Āryabhaṭa

Though Bhāskara was not a direct disciple of Āryabhaṭa it is certain that he belonged to the school of Āryabhaṭa and was one of its important exponents. It may be asked whether it is proper to speak of the followers of Āryabhaṭa as a '*school*' of astronomers. That it was considered a distinct school and that successive generations of astronomers were conscious of belonging to it is evident

---

1. Dr. K. S. Sukla gives the date of Bhāskara as 629 A. D., it is not mentioned on what grounds, in his article 'Acharya Jinadeva, the Mathematician', *Gaṇit*, V. i (June 1954), p. 1. One thing can be said: The answers of the examples on Diophantine problems given by Bhāskara either in the *Mahābhāskarīya* or in the *Āryabhaṭīya-bhāṣya*, cannot be of any help in this matter, for various dates are got, inside and outside our limit, like 527, 622, 642, 643, 666, 867 etc. A. D., and if any date, (like 622), comes close enough probably it is by mere chance.
2. See discussion of precession, *supra*.

from later literature. Bhaskara himself has several references to it: *Cf.* चिरं च जीव्यासुरपेतकल्मषा भटस्य शिष्या जितरागशत्रवः (M.Bh. I. 3); अदृष्टमन्यैरिदमाश्मकीयैः (M.Bh. I. 21); व्याचर्णयन्ति गणका भटशास्त्रचित्ताः (M.Bh. I. 40); अध्वानं गणितविदो भटस्य शिष्याः (M.Bh. II. 5) etc. Lalla also refers to this school[1] in his *Śiṣyadhīvṛddhida* at the beginning of *Grahagaṇitādhyāya*; *cf.*

विज्ञाय शास्त्रमलमार्यभटप्रणीतं
तन्त्राणि यद्यपि कृतानि तदीयशिष्यैः ।

Here the word तदीयशिष्यैः must mean more than the direct pupils of Āryabhaṭa and include Bhaskara too since Lalla is still later.[2] Śaṅkaranārāyaṇa, introducing his commentary on the *Laghubhāskarīya*, mentions a succession of teachers of this school:

आचार्यार्यभटं वराहमिहिरं श्रीमद्गुरुं भास्करम् ।
गोविन्दं हरिदत्तमत्र शिरसा वक्ष्ये प्रणम्य क्रमात् ॥

The omission here of prominent astronomers like Brahmagupta and Lalla who preceded Śaṅkaranārāyaṇa but do not belong to the Āryabhaṭan school is significant. Varāhamihira is included as being great, though not belonging to this school. The peculiarities of the *Āryabhaṭīya*, and its methods of calculation and of explanation are meticulously followed in the works of this school. Tribute

---

1. See also Sudhakara Dvivedi: अहो लल्लसिद्धान्ते प्राचीनानां नामोल्लेखाभावात् सर्वत्र आर्यभटशिष्यैः etc. *Gaṇakataraṅgiṇī*, p. 9.

2. Lalla is later than Brahmagupta whose *Khaṇḍakhādyaka* he has commented upon (*cf.* Āmarāja's *Vāsanābhāṣya* on the *Khaṇḍakhādyaka*:
   लल्लोत्पलसोमेश्वरविरचितभाष्याणि तत्त्वतो बुद्ध्वा ।
   एकीकृत्य तदर्थं सुखाय संक्षेपतो वक्ष्ये ॥ (अवतारिका);
   तथा च खण्डखाद्यकपद्धतौ लल्लः लङ्का, कुमारी, काञ्ची etc. (तिथ्यधिकारः)
   Since Bhaskara is earlier or at the most contemporaneous to Brahmagupta, it follows that Lalla is later than Bhaskara too. The references cited here would incidentally show also that the tradition that Lalla was a direct disciple of Āryabhaṭa and the *Gaṇakataraṅgiṇī* taking him contemporaneous to Āryabhaṭa on the basis of this tradition are wrong.

is paid by followers of this school to Āryabhaṭa bordering on worship.[1]

This school is specially associated with the Kerala country. Practically all the astronomers of this school whose place of origin can be definitely determined belong to this part of India. Probably Āryabhaṭa himself was a native of Kerala. He is called *Āśmaka*, which is derived by commentators as belonging to the Aśmaka country : *Cf.* अश्मकजनपदजात आर्यभटाचार्यः । (Nīlakaṇṭha Somayāji, A. Bh. Bhāṣya on *Gaṇita 1*). And in some quarters it is identified with the southern part of the Kerala state.[2] As for his connection with Kusumapura (Pāṭaliputra) given by आर्यभटस्त्विह निगदति कुसुमपुरेऽभ्यर्चितं ज्ञानम् (A. Bh. *Gaṇita* 1), it is not as a native of that city, but as one who had adopted the Siddhānta venerated and followed by the people of Kusumapura. See for instance Bhāskara's own *Bhāṣya*: कुसुमपुरेऽभ्यर्चितं ज्ञानं, स्वायंभुवसिद्धान्तः।[3] अयं किल स्वायंभुवसिद्धान्तः कुसुमपुरनिवासिभिः कृतिभिः पूजितः, सत्स्वपि पौलिशरोमकवासिष्ठसौर्येषु। तेनाह कुसुमपुरेऽभ्यर्चितं ज्ञानमिति । (*A. Bh. Bhāṣya, page 57*). Two facts may be specially noted here in support of the connection of Āryabhaṭa with Kerala. Practically all the astronomical works produced in Kerala, whether commentatorial or original treatises, follow the Āryabhaṭan school ; also manuscripts of the works of this school are found mostly only in this part of the country.

---

1. See for instance: तपोभिरामं स्फुटतन्त्रमाश्मकं (M. Bh. I. 3), इत्यादि वचनं प्रभोः (M. Bh. V. 12); अयमाचार्यो महानुभावः (Bhāskara's. A. Bh. Bhāṣya, page 6).

2. See V. S. Apte, *The Practical Sanskrit-English Dictionary*. Bombay, 1924 : अश्मकः । Name of a country in the South ; probably an old name of Travancore. (page 181).

3. This is but a synonym for *Brahma* or *Paitāmaha Siddhānta*; It must also be noted here that more than one work went by this name and to-day we know of at least four of them, one which formed the source of Āryabhaṭa, another which is summarised by Varāhamihira in his *Pañcasiddhāntikā* and and two othrs edited by Vindhyesvari Prasad Dvivedi, (Benaras S.S., 1912, 1917) all these differing from one another even in their basic constants.

That Bhāskara identified himself with this school is quite apparent. He refers to Āryabhaṭa in his *Bhāṣyā* as " Our preceptor ", **अस्माकमाचार्यः**, in several places. When in one place he says, " for us the four quarters of the Yugas are equal ", **अस्माकं पुनः युगपादाः सर्वे एव तुल्याः** (p. 32) he identifies himself with the teacher and his school.

The Āryabhaṭīya-Bhāṣya of Bhāskara

As already mentioned, Bhāskara has written three works, the *Mahābhāskarīya*, the *Laghubhāskarīya* and a *Bhāṣya* on the *Āryabhaṭiya*. The *Āryabhṭīya-Bhāṣya* is elobarate and chronologically the last of the three works, since it quotes from the other two. Every page of this work is an evidence to Bhāskara's learning and wide reading. To drive home his point, he quotes maxims freely from the Vyākaraṇa, Vedānta and Mīmāmsā Śāstras. As illustrations, he brings in quotations from the *Arthaśāstra*, the *Manu Smṛti*, a *Viṣa-tantra* and a *Ratnaparīkṣā*. But most of his quotations, especially those pertaining to astronomy, are cited anonymously and it is no easy matter to trace their sources.

We learn from the *Bhāṣya* that besides his *Āryabhaṭiya* which is well-known and his *Ārdharātrika* system, which though not extant, exists in the form of an adaptation in the *Khaṇḍakhādyaka*, Āryabhaṭa was the author of several free stanzas (*Muktakas*); and Bhāskara gives certain of them. Some of these refer to the motion of the Perigees and Nodes of the planets and give the rates of motion of these for the different planets. Though in the Āryabhaṭīya he has not stated that the Perigees and Nodes have motion, still Āryabhaṭa must have held the view that they also have motion as seen from these stanzas. Thus discussing the point whether the Nodes of the planets have motion, Bhāskara says (p. 44) : मुक्तककथितं किलाचार्येण—

एकद्वित्रिचतुरिषून् क्रमशो भगणान् प्रयान्ति सर्वेपास् ।
कल्पादेर्गतकालाद् गणनीयमतो गतिस्तेषाम् ॥

And discussing the motion of the Perigees, he says (p. 46) : अत्र किमिति मन्दोच्चगतिर्नाभिहिता । .... मुक्तकेनैवाचार्येणाभिहितमिति सम्प्रदाया-विच्छेदादवधार्यते । .... अत्यन्तसूक्ष्मत्वात् वर्षगणेनैवाचार्येण यदाख्यातं तदेवाप्यविच्छिन्नसंप्रदायप्रतिपत्त्याभिधीयते । तद्यथा—

अष्टिकृतात्यष्टिनवाजे(?)रुच्चयुगं तिग्मदीधितेरुक्तम् ।

and so on for the other planets. Then why has not Āryabhaṭa given this information in his regular work? It may be because his original, the *Brahma Siddhānta*, did not have it, or because he thought that the motion was so small that there would be very little change of position for a long time to come, or because he was not sure of the amount of motion and therefore gave it tentatively in the form of *Muktakas*, leaving to the future generations the work of verifying and adopting them.

At the end of the Gaṇitapāda, after explaining stanzas 32 and 33 dealing with Diophantine problems (*Kuṭṭaka*), Bhāskara gives a large number of examples, and at the end of these he appends a regular small work of his own on (*Kuṭṭaka*).

The two manuscripts of the *Bhāṣya* available to me are incomplete, the fuller one going only up to the 6th stanza of the *Golapāda*, where it abruptly breaks off. It is however definite that Bhāskara has commented on the whole work since Nīlakaṇṭha Somayāji quotes from the *Bhāṣya* on Golapāda 48[1]. Now, the *Golapāda* is the most valuable part of the *Āryabhaṭīya* from the point of view of spherical astronomy, and Bhāskarā's *Bhāṣya* on this must possess much precious information. It is also likely that at the conclusion of the *Bhāṣya* Bhāskara might have given something about himself, and we are deprived of this information, let us hope, only for the present.

The Mahābhāskarīya

The *Mahābhāskarīya* is an exposition of the astronomical part of the *Āryabhaṭīya*, *i.e.* the *Gītikā*, *Kālakriyā* and *Gola pādas*. What the *Āryabhaṭīya* gives in the from of *sūtra*-like *Āryās*, the *Bhāskarīya* gives elaborately, thus forming an exposition of it. From the frequent references to Āryabhaṭa and the *Āryabhaṭīya* in this work, we can see that Bhaskara has the *Āryabhaṭīya* always before his eye while writing this work. See for instance: कलीकृतं वा ससमं दिवाकरं स्वगीतिकोक्तैर्भगणैः समाहृतम् (I. 9) (Here the use of the word स्व is significant as showing that Bhaskara intends this work as an appen-

---

1. *Cf.* Nīlakaṇṭha Somayāji's work on *Grahaṇa* found at the end of a Ms. of his *Siddhāntadarpaṇa-vyākhyā*, Trivandrum Palace Library, No. 975.

dix to the *Āryabhaṭīya*); निशाकरार्कौ गणकैः प्रकीर्तितौ भटप्रणीताविति बुद्धिमत्तरैः (I. 19) ; त्रैराशिका....भटशास्त्रचिन्ताः (I. 40.); युक्त्या त्रिराशि-सहितश्च भटप्रणीतः (III. 41) ; भास्वतो ग्रहणं वाच्यमाचार्यार्यभटोदितम् (V. 1.); मध्यलग्नमिदं स्पष्टं श्रीमद्भटमुखोदितम् (V. 11.); ज्ञापकं च स्वदृक्क्षेप इत्यादि वचनं प्रभोः (V. 12); प्रोक्तमेतत्....कर्म...विदुषा....समर्पितम् (V. 78); उच्यतां भटतन्त्रविदाऽऽशु (VIII. 19); सम्यगार्यभटकर्मनिबन्धः (VIII. 24).

Further, Bhāskara has not given the table of sines which should necessarily be given in an independent work, but refers the readers to the *Āryabhaṭīya*, saying, जीवा मख्यादयो मताः (VII. 26), लिप्तीकृत्य हरेन्मख्या (IV. 3) etc. His treatment of *Kuṭṭaka* (I. 41-52) is so compendious in spite of its being an exposition of the two *Kuṭṭaka sūtras* of Āryabhaṭa (*Gaṇitapāda* 32-33), that it can be understood only when the same topic in his *Bhāṣya* is studied. Everything he gives by way of constants and methods of computation agree with the *Āryabhaṭīya*, and what is more, there is nothing that goes against it, not even *Bīja*-corrections, which, according to Hindu astronomical tradition, is not going against the original work. In order to give all that Āryabhaṭa has given to the world, Bhāskara describes Āryabhaṭa's *Ārdharātrika* system too at the end of ch. VII.

Speaking of the *Mahābhāskarīya*, the Kerala astronomers look upon Āryabhaṭa as the *Sūtrakāra*, Bhāskara as the *Vṛttikāra*, and Govindasvāmin, the author of the *Bhāskarīya-bhāṣya*, as the *Bhāṣyakāra*. Practically this is so, but it must not be taken literally, because the *Gaṇitapāda* is almost wholly omitted in the *Bhāskarīya*, as it naturally should be, considering the subject matter, and also because Govinda's *Bhāṣya* is only *Bhāskarīya*-*Bhāṣya* and not *Āryabhaṭīya Bhāṣya*. Govindasvāmin himself calls the *Bhāskarīya* a *Vṛtti* of the *Āryabhaṭīya* in his concluding stanza:

आचार्यार्यभटः पितामहमतं तन्त्रं सुसंक्षिप्तवान्
वृत्तिं विस्तरतोऽस्य मन्दमतये तेनाकरोद् भास्करः।

(page 394)[1]

and the *Siddhāntadīpikā* echoes him (p. 2, 395).[2] From several passages in Govindasvāmin's *Bhāṣya*, it would seem that he takes the

1, 2. Page references to Govindasvāmin's *Bhāyṣa* and Parameśvara's *Siddhāntadīpikā* thereon, are to the present publication.

Āryabhaṭīya and the *Mahābhāskarīya* as constituting one whole; *Cf.* for instance: आचार्यार्यभटाभिमत ग्रहकर्मणां निबन्धनं चिकीर्षुः (p. 1); तस्मादार्यभटाभिमतग्रहगत्युपायविवरणं करिष्यामः इत्येतदर्थादापन्नम (p. 3); कुतः पुनः शशाङ्कमासावगतिः? अध्यायाष्टकपाठाभावादिति चेत्, सत्यम्।...... एते कालक्रियापादे [भास्करकृत-आर्यभटीयभाष्ये] सविस्तरं विवृतत्वात् तत एवावगन्तव्या इति भावः। (p. 6); सकलं साग्रकुट्टाकारगणितं गणितपादे [भाष्ये] विस्तरेणोपन्यस्तम्। तदत्रापि सूचितम्। (p. 76); गोलपादे भाष्ये वक्ष्यति। (p. 143); मन्द! मैवमाचार्यार्यभटाभ्युपगमः। (p. 166); ननु छायागणितेनैव [गणितपादे] छायादैर्घ्ये सिद्धे पुनस्तद्दैर्घ्यकथनमनर्थकम्। सत्यमेतत्। (p. 317); तत्र तावदाचार्येण गीतिकासूक्तं यदागमेन विना अवगन्तुमशक्यम्। तस्मादिह यदागमैकशरणमभिधीयते तत् तत्रैवान्वेषणीयम्। एवं सर्वत्र अन्विष्यान्विष्य योजनीयम्। (p. 375). Śaṅkaranārāyaṇa too at the beginning of his commentary on the *Laghubhāskarīya* says: "अत्रादौ किल विश्वसृड्वदनजं......पैतामहं......आर्यभटः प्रपञ्चरहितं स्वैनैव नाम्नाकरोत्। तद्व्याख्याननिबन्धत्रयमलं श्रीभास्करोक्तं..." from which we see that he looks upon all the three works of Bhāskara as commentaries on the *Āryabhaṭīya*.

An indication of where in the *Mahābhāskarīya* the various topics of the *Āryabhaṭīya* have been elaborated may be made here. The matter of the *Gītikāpāda* is mostly found in ch. VII of the *Mahābhāskarīya*, the radius in *yojanas* of the orbits of the sun and the moon, and the diameter of their orbs, alone being given in ch. V, in connection with eclipses. Govindasvāmin quotes all the ten *gītikās* excepting the 8th (giving the epicycles relating to the Equation of the centre) and the 10th (giving the Sine segments). The *Gaṇitapāda*, of course, cannot normally find a place in the *Mahabhaskariya*; but stanzas 32-33, dealing with *Kuṭṭaka*, are elaborated in I. 41-52. Of the total thirty-three *āryās*, Govindasvāmin's *Bhāṣya* quotes ten in the explanations. The matter of the *Kālakriyāpāda* is principally found in ch. IV, and a small portion in ch. VII, used in the latter to get the derived constants like the synodic months in the *yuga* etc. Of the twenty-five *āryās* in this *pāda*, only nine (4, 8-11, 16, 20, 21, 23) are left out unquoted by Govindasvāmin. Of these nine, 4b, 8-11 and 16 deal with matter usually met with in the *uttarabhāga* of an astronomical treatise and therefore not taken up by Bhāskara for treatment. This leaves only 20, 21 and 23 as unquoted.

The matter of the *Golapāda* is contained in chs. III, V and VI. The matter covering what is called *Tripraśna* is given in the third

chapter. Eclipses are dealt with in the Fifth, and miscellaneous things like the Heliacal Rising and Setting of planets. Elevation of the Moon's horns, Planetary Conjunctions etc. are given in the Sixth. Of the fifty *āryās* in this *Pāda*, Govindasvāmin quotes all except five (22, 23, 46, 49, 50). Of these 49-50 are concluding verses not dealing with astronomical matter. 22-23 deal with making the *Gola-yantra*. 46 deals with the 'colour of the eclipse', which astronomers usually give in their works but Bhāskara has chosen not to give. Thus we find that almost all the *āryās* of the *Āryabhaṭīya* are seen by Govindasvāmin reflected in the *Mahabhaskariya*, and interpreted against that background.

Noteworthy points in the Mahābhāskarīya

A Summary of Contents of the *Mahabhaskariya* is given after the Introduction. Here, however, may be noticed, what is specially noteworthy in the work as being an exposition of the school of Āryabhaṭa and what is special to Bhāskara.

The Mean Planets etc. through Pratyabda-śodhana

In I. 21-40 Bhāskara gives his own method to find the Mean Planets, the Śīghra of Venus and Mercury, and the Perigee and Node of the Moon, saying that the method was not known to the other members of Āryabhaṭa's school (*Āśmakīyas*). The method consists in first finding the Mean Sun by a shortcut called *Pratyabda-śodhana* and using the Mean Sun to find the Mean etc. of the other planets. This idea he might have copied from the Romaka school, for he himself says in his *Āryabhaṭīya-Bhāṣya* (p. 196): अथ अत्र रोमकाः प्रत्यब्दशोधनेन आदित्यमानयन्ति, तेन चादित्येन सर्वानपि, and then he goes on to explain what is *Pratyabda-śodhana* and refers us to M. Bh. I. 22-25. (For details of the method given, see *Summary of Contents*, below).

Indeterminate Analysis

In I. 41-52 Bhāskara deals with the solution of Inderminate or Diophantine Equations (*Kuṭṭaka*) of the First degree, though the subject is only remotely connected with astronomy proper. As already mentioned this section is an exposition of *Āryabhaṭīya, Gaṇita* 32-33. Both the main types, Niragra Kuṭṭākāra and Sāgra Kuṭṭākāra are dealt with, for details of which see Summary of Contents.

The absence of Anyanāṁśa

A noteworthy feature in Chapter III is that no *Ayanāṁśa* (Degrees of precession) is mentioned here, though this is necessary and usually given in the Siddhāntas. This chapter deals with *Tripraśna* and formulae are given to compute the declination, shadow, direction etc. of the Sun and other planets. In these computations the longitudes of these are to be reckoned from the Vernal Equinox, *i.e.* the point where the Ecliptic crosses the Celestial Equator northwards. This longitude is called the *Sāyana* or Tropical longitude, *i. e.* the longitude with the *Ayanāṁśa added*, and the *Ayanāṁśa* forms the distance between the Vernal Equinox (VE) and the starting point of the fixed *Sign* Meṣa (Aries), from which latter point the longitudes are reckoned. The VE has a backward movement (called the Precession of the Equinoxes, which implies the precession of the Solstices as well, and is therefore called *Ayana-calana*) at the rate of about 50.25 seconds a year, and the *Ayanāṁśa* is continuously increasing at this rate. It coincided with the starting point of Meṣa (we shall call this point M) at about 562 A.D., and so the *Ayanāṁśa* was zero then.

Now at the time of Āryabhaṭa (499 A. D.) the VE was east of M only by about 50', and so he could not distinguish between the two points. During the time of Bhāskara (*c.* 600 A. D.), the VE was west of M by only a little more than half a degree, and he too could not distinguish between the two points. This is the reason why neither Āryabhaṭa nor Bhāskara has given any *Ayanāṃśa*. More than this, Bhāskara held the view that there was no such thing as *Ayanāṁśa* or *Ayana-calana*[1] and probably Āryabhaṭa too held the same view. In the Āryabhaṭīya-Bhāṣya Bhāskara discusses the question of precession (pp. 175-76), criticises the Romakas (who say there is precession, state reasons for their view and also give the rate of precession), and also tries to establish that there is no precession, characterising the Romakas as people who did not know the truth:

---

1. The act or rate of precession is called *Ayana-calana*, and the amount of precession accumulated thereby is called *Ayanāṃśa*.

cf. अप्यत्र अविदितपरमार्थाः रोमकाः पठन्ति—

वसुदैवादिसार्पार्धादयनं मुनयो जगुः ।
मृगकर्क्यादितो दृष्टं कथं तद्धि गतेर्विना ॥[1]

इत्यादि...... । युगभगणानाहुस्तत्र—वियद्रुद्रकृतनन्दघृती...सप्तविश्वाख्यान् । Bhāskara explains the fact that the Winter and Summer Solstices, *i.e.* the beginnings of the northward and southward courses, have shifted from the beginning of Śraviṣṭhā and the middle of Āśleṣa in ancient times to the beginning of Makara and the beginning of Karkaṭaka in his own times, by saying that it is not a regular astronomical phenomenon but an irregular phenomenon of the nature of an omen (*utpāta*).

Varāhamihira's view on Ayana-calana

Incidentally we may examine here Varāhamihira's view on this point, for he too belongs to the same period (505 A.D.). Varāha mentions the shifting of the Solstices in his *Pañcasiddhāntikā* and the *Bṛhatsaṃhitā :*

आश्लेषार्धादासीद् यदा निवृत्तिः किलोष्णकिरणस्य।
युक्तमयनं तदासीत्, सांप्रतमयनं पुनर्वसुतः ॥ (*Pañca-S*. III. 21)

आश्लेषार्धाद्दक्षिणमुत्तरमयनं रवेर्धनिष्ठाद्यम् ।
नूनं कदाचिदासीद् येनोक्तं पूर्वशास्त्रेषु ॥

सांप्रतमयनं सवितुः कर्कटकाद्यं मृगादितश्चान्यत् ।
उक्ताभावो विकृतिः प्रत्यक्षपरीक्षणैर्व्यक्तिः ॥ (*Bṛhatsaṃhitā* III. 1-2)

'Certainly there was a time when the Summer Solstice was at the middle of the Āśleṣa segment, and the Winter Solstice at the beginning of Dhaniṣṭhā, *i.e.* Śraviṣṭhā segment; that was why the ancient works (like the *Vedāṅga Jyotiṣa* and the *Garga Saṃhitā*) have mentioned such a fact. But now the Summer Solstice is at the beginning of the Karkaṭakarāśi-segment (*i.e.* at the end of three quarters of the Punarvasu segment) and the Winter solstice is at the beginning of the Makara rāśi segment. If the Solstices are

---

1. "The sages have said that the Sun's northward and southward courses began when it was at the beginning of the Śraviṣṭhā segment and the middle of the Āśleṣa segment respectively. But now the beginning of the courses are seen to be at the first points of the Signs Makara and Karkaṭaka respectively. How can this be if there is no precession ?"

not found in the stated places[1] (in any future time) they would have shifted still further, and the amount of shift (called *Vikṛti*) is to be found by observation."

We can be certain that Varāhamihira considered this shift as a gradual and natural phenomenon[2] because, he, who had condensed the *Romaka-Siddhānta*, must have known that the Romaka year is Tropical, *i.e.* from Equinox to Equinox, and its shortness in comparison with the Siderial year given by the other systems, was explained by the Precession of the equinox, especially when the Romakas had held this theory, as seen from the stanza quoted by Bhāskara. But because he was not sure of the rate of precession he could not give it in the form of a formula, and therefore must have advised observation to find the actual amount of precession.[3]

Another point must be made clear, namely, the *Ayanāṃśa* was zero or nearly zero, as already mentioned, during the period we are considering (*c.* 500-600). When Varāhamihira wrote the *Pañcasiddhāntikā* (just after 505 A. D.)[4] the VE was only 47 minutes east of M, and this being within the limits of probable observational error, he too took the VE as coincident with M, and it has already been noticed that M, *i.e.* the starting point of Meṣa is marked by the VE of 562 A. D.

---

1. Nīlakaṇṭha Somayāji in his *Āryabhaṭīya-Bhāṣya*, *Kāla* 10, gives the reading *uktā bhāṁśaiḥ* in the place of *uktābhāvo*. According to his reading the meaning is: It is said that the shifting may go up to twenty-seven degrees. The actual amount of shift is to be found by observation.'

2. This is not against his own *Bṛhatsaṁhitā*, III 4-5, where he gives the shifting as an omen, .for natural phenomena can also be omens.

3. Bhāskarācārya II has given similar advice: अथ च ये वा ते वा भगणाः (क्रांतिपातानां) भवन्तु। यदा येंऽशाः निपुणैरुपलभ्यन्ते तदा त एव क्रांतिपात इत्यर्थः। (*Siddhāntaśiromaṇi*, *Golādhāya*, *Golabandha*, 19).

4. Some people say, without sufficient reason, that the date of the work is some years later. But this does not affect our point.

D. V. Ketkar's view examined

D. V. Ketkar, son of V. B. Ketkar, however, in a recent pamphlet of his, *Date of Kalidas (A. D. 240-300)*[1] and in his introduction to his father's *Jyotirgaṇitam*, takes the VE of 280 A. D. as the starting point of Meṣa, and states that at Varāha's time there was a precession (*Ayanāṁśa*) of about 3 degrees 20 minutes. At Bhāskara's time it would be still more. If true, this factor would have to be taken into account in working out the true planets, eclipsees, etc. according to the *Bhāskarīya* (as also other works of the period). This matter, therefore, must be considered in detail, and decided.

It may be noted at the outset that no Indian work on astronomy has said either implicitly or explicitly that there was an *Ayanāṁśa* of 3° 20' during this period. On the other hand they have all either taken implicitly or said explicitly that the *Ayanāṁśa* was zero, and so if it is asserted, as D.V. Ketkar does, that the Ayanāṁśa was 3° 20' or thereabouts at this period, it is equal to asserting that all Indian astronomers are either wrong or ignorant. I shall explain how.

Many Siddhāntas give a point 10' east of the junction-star of Revatī as M. This star can be only Zeta Piscium and no other, because no other star in the neighbourhood can answer to the description of its being on the ecliptic according to every Siddhānta, and also because other stars will be too far away from the positions in dispute. For example: Delta Piscium is about 7° west of Zeta and has a latitude of 2° N; Epsilon Piscium is about 3° west, and its latitude is about $1\frac{1}{4}$° N; Eta Piscium is about 5° east and has a latitude of more than $5\frac{1}{2}$° N; Nu Piscium is about $7\frac{1}{2}$° east and has a latitude of about 5° S: Omicron Piscium is about $8\frac{1}{2}$° east and its latitude is about 2° S. It must be noted that only Eta Piscium was sufficiently near[2] the VE of 280 A.D. in longitude, but its latitude being $5\frac{1}{2}$° from the ecliptic, it could not have been described as being on the ecliptic. So Zeta Piscium must be the junction star of Revati. Now it happens that this star is of comparatively small magnitude, and on this account scholars like Thibaut doubt its being the junction-star of Revati. But it must be remembered that its nearness to the ecliptic must have been an overweighing consideration with the ancient astronomers who first chose the junction-stars.

---

1. Pub. Ketkar's Astro-Mathematical Series, Bijapur, 12 pp.
2. This too is so only if we are prepared to assume an observational error of $1\frac{3}{4}$°.

Thus many Siddhāntas like the *Sūrya Siddhānta*, the *Brahma Siddhānta* and the *Vṛddha Vāsiṣṭha* give 10' east of Zeta Piscium as M. The *Soma Siddhānta* gives 30' east of this star as M, (unless the longitude which this Siddhānta gives for this star, 359° 30', is a mistake for 359° 50' as in the *Sūrya Siddhānta*, which is very likely). The *Mahābhāskarīya*, the *Brahmasphuṭa Siddhānta* and the *Siddhānta Śiromaṇi* following the *Brahmasphuṭa Siddhānta*, give Zeta Piscium itself as M. We thus see that there is not much difference among the Siddhāntas on this point, and we can safely conclude that these Siddhāntas agree in giving a point about 10' east of Zeta Piscium as M.

Now the VE was actually at M in 562 A.D. as we have already stated. In this matter too all the Siddhāntas are agreed within the limits of observational error, which does not exceed one degree in any case, (a close result indeed when considering the difficulty of the observation). This we shall see now. The *Sūrya*, *Brahma*, *Soma* and *Vṛddha Vāsiṣṭha Siddhāntas*, together with many other later Siddhāntas and Karaṇas that give rules for *Ayanāṁśa* make it clear that the *Ayanāṁśa* was zero, *i e.* VE and M coincided, at the end of 3600 Kali 499 A.D.). This would imply an observational error of about only 53minutes; (in the case of the *Soma Siddhānta* if we take its longitude of Zeta Piscium as correct, it is still less). The rule of Muñjāla's *Laghumānasa*[1] gives zero *Āyanāṁśa* at 527 A.D. which means an observational error of 29 minutes only. The *Āryabhaṭīya*, the *Pañcasiddhāntikā*, the *Mahābhāskarīya* and the *Brahmasphuṭa Siddhānta* which belong to this period all tacitly take it that the VE and M coincide at their times, by not distinguishing between the ordinary longitude reckoned from M used for giving the position of the planets, and the Sāyana longitude reckoned from the VE for finding the declination etc. The observational error for the *Āryabhaṭīya* (end of 499 A.D.) is 53', for the *Pañcasiddhāntikā* (end of 505 A.D.) 47', for the *Mahābhāskarīya* (c. 600 A.D.) about 32', on the other side, (only about 24' if we take *its* longitude for Zeta Piscium) and for the *Brahmasphuṭa Siddhānta* (628 A.D.) 55', (only about 47' if we take its longitude for Zeta Piscium). Thus it is seen that all Siddhāntas either state or accept that during the time of Varāha-

---

1. Referred to by Bhāskarācārya II in his सि. शि., गोलाध्याय, गोलबन्ध, 18.

mihira's *Pañcasiddhāntikā*, there was no *Ayanāṁśa*, and that the VE of that period (and not the VE of 280 A.D.) marks the starting point of Meṣa.

D. V. Ketkar's contention in his pamphlet and the Introduction cited above, that there was an Ayanāṁśa of 3° 20' according to Varāhamihira in his own time (c. 520 A. D. according to Ketkar) can be shown to be untenable. Varāhamihira says that the Vernal and Autumnal Equinoxes were at the beginning of the Signs Meṣa (Aries) and Tulā (Libra), and that the Winter and Summer Solstices were at the beginning of the Signs Makara (Capricorn) and Karkaṭaka (Cancer). Cf. मेषतुलादौ विषुवत् *Pañca-S*. III. 23; उदगयनं मकरादौ दक्षिणमयनं तथा च कर्कटकात् । *ibid*. III. 25 ; सांप्रतमयनं सवितुः कर्कटकाद्यं मृगादितश्चान्यत् । *Bṛhat-S*. III. 2, and this implies *zero Ayanāṁśa*. These cannot be explained away by saying that these are *Sāyana* Meṣa etc. as Ketkar does : *Cf*. वराहोक्तोऽयं कर्कटकादिस्सायनः, तेन सायनकर्कटकादिरत्र निरयनपुनर्वस्वर्ध एव भवति । (Introduction to his father's *Jyotirgaṇita*). If they are *Sāyana* it must be said so somewhere in the context, but nowhere does Varāhamihira say so. Further if it is *Sāyana* Karkaṭaka, there is no meaning in saying: सांप्रतमयनं सवितुः कर्कटकाद्यम् । *i.e.* '*now* (*sāmpratam*) the Summer Solstice is at the beginning of Karkaṭaka, for it falls always at *Sāyana* Karkaṭaka; (vide also the quotation from the *Romaka Siddhānta*, above). Another reason why Varāha's Meṣa etc. could not be *Sāyana*, and therefore there could not be an *Ayanāṁśa* of 3° 20', is this: If we compute the longitudes of the Sun, Moon etc. for Varāha's time by his Siddhāntas, and by modern astronomy, taking the *Ayanāṁśa* as zero, they agree closely. If the *Ayanāṁśa* were 3° 20′ there is a difference equal to this amount which is too great to be considered an error of the Siddhāntas. If it is argued that the longitudes are *Sāyana* (Tropical) as, in the Romaka, this is inconsistent with the clearly siderial periods given for the Sun, Moon etc. So there could not be an *Ayanāṁśa* of 3° 20' during Varāha's time.

In fact there is no such thing as *Sāyana* Meṣa etc., these being only convenient ways of saying 'Meṣa etc. with the *Ayanaṁśa* added', *i.e.* placed behind them. Actually Meṣa etc. are fixed Rāśi segments of the ecliptic, constituted by the fixed Nakṣatra segments taking two and a quarter for each Rāśi, and therefore cannot be reckoned from the movable Vernal Equinox. So statements like 'the beginning of Karkaṭaka' can mean only 'the point at the end of three quarters

of the Punarvasu segment' etc. This fixed relationship with the fixed Nakṣatra segments is stressed by statements like :

आश्लेषार्धाद्दक्षिणमुत्तरमयनं रवेर्धनिष्ठाद्यम् ।
नूनं कदाचिदासीद् येनोक्तं पूर्वशास्त्रेषु ॥

सांप्रतमयनं सवितुः कर्कटकाद्यं.........

वसुदैवादिसार्पार्धादयनं मुनयो जगुः ।
मृगकर्क्यादितो दृष्टं कथं तद्धि गतेर्विना ॥

where the terms कर्कटकाद्यं and मृगकर्क्यादितो in juxtaposition with आश्लेषार्धं etc. can only mean the beginning of Karkaṭaka related to the Nakṣatra segments, *i.e.* the end of three quarters of Punarvasu.[1] Also from सांप्रतमयनं कर्कटकाद्यं and मृगकर्क्यादितो दृष्टं above, we understand that it was so at the time of Varāha and not at any earlier time like 280 A.D. That it is three quarters of Punarvasu and not half as stated by D.V. Ketkar in his pamphlet, p. 5 is reinforced by Varāha's statement implying that there is a difference of one and three quarters Nakṣatra segments between the Summer Solstice occurring at the middle of the Āśleṣa segment at an ancient time (actually it is the time of the *Vedāṅga Jyautiṣa*) and in Punarvasu in his own time. Varāha says:

[2]अर्केन्दुयोगचक्रे वैधृतमुक्तं, दशार्क्षसहितेषु ।
यदि चक्रो व्यतिपातः.........
आश्लेषार्धादासीद् यदा निवृत्तिः किलोष्णकिरणस्य ।
उत्तरमयनं तदासीत् सांप्रतमयनं पुनर्वसुतः ॥

Pañca-S. III. 20–21

Here दशार्क्षसहितेषु यदि चक्रो व्यतिपातः can be explained only by a precession of one and three quarters Nakṣatra segments, which, affecting the longitudes of the Sun and the Moon by one and three quarters Nakṣatra segments each, accounts for the three and a half segments (because Sun plus Moon is taken in the Yoga) required in the explanation (For details see Thibaut's explanation under his

---

1. The statements would be meaningless as connecting unrelated things if the fixed Karkaṭaka and Makara segments are not meant.

2. I give the reading of the manuscript text in Thibaut's edition, and not his emended reading; but it does not affect the matter in question here.

translation of III. 20 and Sudhakara Dvivedi's commenatry on the verse, in their edition of the work). The Summer Solstice retrogressing one and three-fourths segments from the middle of Āśleṣa will be at the point three-fourths Punarvasu, and no other. Now Ketkar has not noticed this point at all. On the other hand he relies upon the reading of Nīlakaṇṭha Somayāji referred to previously, "उक्ता भांशैर्विकृतिः," to maintain his theory of a precession of two Nakṣatra segments, (*i.e.* from Āśleṣa half to Punarvasu half) and feels triumphant over it saying, 'Nīlakaṇṭha's authoritative statement reached our hands in 1933. Today the date B. C. 1400 (for the *Vedaṅga jyautiṣa*) stands unchallenged.' (*Date of Kālidās*, p. 4). Now Bhaṭṭotpala's reading उक्ताभावो विकृतिः is certainly more authoritative than Nīlakaṇṭha's, he being earlier than the latter by several centuries. Again, a perusal of Nīlakaṇṭha's *Bhāṣya* of the *Āryabhaṭīya*, *Kālakriyā*, 10, would show that Nīlakaṇṭha states definitely that at the time of Āryabhaṭa (which is also the time of Varāha) there was no *Ayanāṁśa*, and this statement is against Ketkar's theory, and that by *Bhāṁśa* Nīlakaṇṭha means only the maximum precession or procession of exactly 27° mentioned in Hindu astronomical works, and not two Nakṣatra segements in whole number of degrees as Ketkar thinks. Thus Nīlakaṇṭha's reading does not support Ketkar, but actually goes against him.

There is also the statement of Bhāskarācārya II to show that during Varāha's time the *Ayanāṁśa* could not be so large as 3° 20'. Speaking of *Ayanāṁśa* he says: किमिति ब्रह्मगुप्तादिभिः निपुणैरपि नोपलब्धः? तदानीं स्वल्पत्वात् नोपलब्धः। (*Siddhānta-Siromaṇi*, *Golādhyāya*, *Golabandhādhikāra*, 17-19): 'Why is it that experts like Brahmagupta and others (Varāha is included under 'others') have not observed any *Ayanāṁśa*? Because it was small during their period they have not noticed it.' Here D. V. Ketkar tries to save his theory by stating that 3° 20' was meant by Bhāskara as small. Now, 3° 20' is not so small as unobservable. (Note that all the observational errors previously mentioned are less than one degree, some far less). Further in Brahmagupta's time (628 A. D.) the Ayanāṁśa would be about 5 degrees, if it was 3° 20' in Varāha's time, (taking his date as 520 A. D. according to Ketkar), and an Ayanāṁśa of 5° is certainly not so small as to be unobservable, especially by an expert like Brahmagupta.

We shall now consider why in the face of this concensus of opinion for Zero *Ayanāṁśa* during the period of Varāha,

Ketkar says it is 3° 20'. It is his view that the beginning of the star-segment Śraviṣṭhā is situated at the *star* Śraviṣṭhā itself and not about 3° west of it as all astronomers have taken.[1] So the starting point of Aśvinī (which is the same thing as saying the beginning of Meṣa) for him is about 3° east of the starting point taken by all the astronomers, and this is the *Ayanāṁśa* 3° 20', which he speaks of. He bases his view that the star Śraviṣṭhā itself is the origin of the Śraviṣṭhā segment upon the following:

स्वराक्रमेते सोमार्कौ यदा साकं सवासवौ ।
स्यात्तदादि युगं माघः तपः शुक्लोऽयनं ह्युदक् ॥

प्रपद्येते श्रविष्ठादौ सूर्याचन्द्रमसावुदक् ।
सार्पार्धे दक्षिणार्कस्तु माघश्रावणयोः सदा ॥

(*Yājuṣa Jyautiṣa* 6-7)

कालज्ञानं महत्पुण्यं कालश्चादित्य उच्यते ।
स च माघस्य शुक्लादौ सोमवासवयोः सह ।
सहोदयं श्रविष्ठाभिः प्रस्थायाह्नामुदङ्मुखः ॥

(Quoted by Ketkar in his Introduction to *Jyotirgaṇitam*, with the prefix तथा च गर्गः)[2]

In the two *Yājuṣa Jyautiṣa* ślokas quoted above, it is said that the Five-year cycle, the Sun's northward course, the month of Māgha etc. commenced with the Sun and Moon rising together in the

---

1. This is seen from all of them giving a longitude of about 296° 15' for Śraviṣṭhā, (Bhāskara I gives 296°.), while the Śraviṣṭhā segment commences at 293° 20'.

2. It is not given from which work of Garga this quotation is taken. But another quotation from the same Garga given by Somākara in his commentary on the *Vedāṅga Jyautiṣa* gives only this much:

   यदा माघस्य शुक्लस्य प्रतिपद्युत्तरायणम् ।
   सहोदयं श्रविष्ठाभिः सोमार्कौ प्रतिपद्यतः ॥

   Here there is no mention of Vāsava and Śraviṣṭhā together, which would require us to interpret one as the actual star group.

Śraviṣṭhā segment beginning with the Winter Solstice. There is nothing here to connect the position of the star Śraviṣṭhā with the Sun and the Moon rising together. There is nothing therefore in these to support Ketkar's view. But in the quotation from Garga above, the star Śraviṣṭhā also is mentioned as rising together with the Sun and the Moon, and Ketkar's view is solely based on this. This would support Ketkar only if Garga had meant the exact equality in longitude of the junction star Śraviṣṭhā with the Sun and the Moon, and only if Garga could have made this observation with such exactitude. But Garga could not and should not have meant the exact equality in longitude because if it is to answer this description there would not be a Five-year cycle at all, the Sun and the Moon in conjnction being at varying points in the segment at each succession of five years. Further, the conjunction being of the Mean Sun and Moon, they might actually be more than 6^0 apart, and rising together with Śraviṣṭhā Star would be meaningless if meant literally. Also it is very doubtful if at such an ancient time people had ever thought of a junction star, and so all that Garga had meant might have been only the star-group Śraviṣṭhā; (notice the plural Śraviṣṭhābhiḥ).

As for correct observation, it should have been impossible in those days even within some degrees of accuracy, when we consider the following points: (i) The observation can be done only indirectly and not directly, because the conjunction of the Sun with a star cannot be observed directly. (ii) Śraviṣṭhā is too far off the ecliptic (about 36^0) to be measured in longitude within the required degree of accuracy, especially for the astronomers of such an ancient period. So all that Garga should have meant was a very rough sort of conjunction from which no conclusion can be arrived at as regards the exact position of the star in the stellar segment. Thus D. V. Ketkar's thesis that there was an *Ayanāṁśa* of 3° 20' at the time of Varāhamihira is untenable. Therefore in the period, from Āryabhaṭa to Bhāskara I, the *Ayanāṁśa* was in the neighbourhood of zero.

Lastly one other point may be noted here. Taking the point on the ecliptic 10' east of Zeta Piscium, *i.e.* the Vernal Equinox of 562 A. D., as the starting point of the sign Meṣa, the *Ayanāṁśa* for 1900 is 18^0 37'. Or assuming as correct the implied or expressed statement of most of the Siddhāntas that the *Ayanāṁśa* was zero at 3600 Kali (499 A.D.), the *Ayanāṁśa* for 1900 is 19° 29'[1]. But

1. Of the two the former is a more proper assumption.

according to the *Ayanāṁśa* adopted by most almanac-makers who base their almanacs on the Western system and the Nautical Almanac, the adopted *Ayanāṁśas* for 1900 are in the neighbourhood of 22½°. These *Ayanāṁśas* would appear like lending support to Ketkar's theory. They would, if they are based on astronomical grounds. They are not so based, but based on expediency. Though these almanac-makers have wished to produce a correct almanac, they have felt afraid of making drastic changes in the old almanacs ; and the adoption of the correct 18° 37' (or 19° 29') Ayanāṁśa for 1900 would entail great changes like fixing the Ravi-Saṅkramaṇas three (or even four) days earlier than they would occur in the old-system almanacs;[1] and there would be a hue and cry raised against the new almanacs. Thus it is on the instinct of self-preservation and not on astronomical grounds that these *Ayanāṁśas* are based and as such, they cannot support the view that there was an *Ayanāṁśa* of 3° 20' at the time of Varāha.

In Ch. IV in the computation of the True planets from the Mean, both the Excentric and the Epicyclic methods are elaborately given as alternatives.

Use of the True Hypotenuse in the Equation of the Centre

In calculating the Equation of the Centre the related True Hypotenuse or *Aviśiṣṭa Mandakarṇa* is taken into account. The use of the Mandakarṇa is unusual, and forms a characteristic of the school of Āryabhaṭa. (See *Summary of Contents*, IV. 8b-12). It may be noted here that Bhāskarācārya II in his *Siddhānta-Śiromaṇi*, (*Golādhyāya, Chedyaka*, 36-37) opposes this and defends the usual practice.

---

1. The reason why the Ravi-Saṅkramaṇas are later by several days in the old-system almanacs is that the Hindu siderial year is about 9 vināḍis longer than it actually is, so that accumulating through the fourteen centuries upto 1900 it has come to about 3½ days. Corresponding to this, they have made their rate of precession considerably longer (even one minute per annum), which amounts to a *procession* of the First point of Meṣa at the rate of about 9 seconds per annum, accumulating to about 3½ degrees, at about 1900.

True Mercury and Venus

In the matter of computing the True Mercury and Venus the first Manda operation of the four operations usually done, is dispensed with. This too is a characteristic of the School of Āryabhaṭa. (See *Summary of Contents*, IV. 43, 51b-53).

Reduction to the Equator

The Reduction to the Equator (*Udayāntara*) is absent as in the case of the works before Śrīpati, in whose *Siddhāntaśekhara* it appears for the first time.

The Mahāpātas

The three Mahāpātas, *Vyatīpāta*, *Vaidhṛta* and *Sārpamastaka*, alone are given, and the group of *Twenty-seven Yogas*, Viṣkambha etc., are not given. The first dated work in which the *Twenty-seven Yogas* appear is the *Brahmasphuṭa Siddhānta*. They are also found in the *Sūrya*, *Brahma*, *Soma*, *Vāsiṣṭha* and *Paitāmaha* (of the *Viṣṇudharmottara*) Siddhāntas, about whose dates we are not certain. Bhāskara who comes just before Brahmagupta must have known the *Viṣkambha* etc. *Yogas*, but he has not given them in his works probably because Āryabhaṭa has not mentioned them. But it is strange why he does not speak about them in his *Āryabhaṭīya-Bhāṣya* where he discusses so many extraneous things connected with the topics in question. Thus in the *Bhāṣya on Kāla*. 3 (p. 171) he says that the Mahāpātas given by the *Āryabhaṭīya* are rough—he himself gives only these rough Pātas in the *Mahābhāskarīya*—the latitude of the Moon not being taken into consideration, and says how they are to be made exact: एवं स्थूलव्यतीपातभुक्तिः यथा सूक्ष्मो भवति तथा प्रदर्श्यते । उक्तम्—

नानायने व्यतीपातः तुल्यापक्रमयोस्तयोः ।
उद्देशास्तस्य चक्रार्धं विक्षेपात्त्वधिकोनकम् ॥

The roughness of the Mahāpātas mentioned above is a stage in their long history. In the *Vedas* or the *Vedāṅga Jyautiṣa*[1] nothing is said about any of the Mahāpātas or Yogas. In the works of the subsequent period the Vyatīpāta alone is found. The *Paitāmaha Siddhānta* in the *Pañcasiddhāntikā* gives a rule to find the *Vyatīpāta*, from which we can infer that the original *Paitāmaha Siddhānta* must

---

1. Shama Sastri fancies seeing it in the *Vedāṅga Jyautiṣa*.

have had it. It is defined thus: When the longitudes of the Sun and the Moon are together equal to 12 Rāśis, it is Vyatīpāta, longitude here being reckoned from the Winter Solstice, which was then at the beginning of Śraviṣṭhā. The two characteristics of *Vyatīpāta*, that the Sun and the Moon should be in different *ayanas* and that they should have the same declination, are secured by this definition;[1] only the longitudes are mean and the latitude of the Moon is not taken into account in considering its declination.

Next, the *Āryabhaṭīya* in *Kālakriyāpāda*, verse 3 says: रविशशिनक्षत्रगणाः साम्मिश्राश्च व्यतीपाताः and this is interpreted as giving in a rough manner the two types of Mahāpātas, *Vyatīpāta* and *Vaidhṛta*. It is while commenting upon this that Bhāskara says that the true declination of the Moon which is obtained by taking into consideration the latitude of the Moon is to be used, which means that the words 'Six Rāśis's mentioned in the definition of the *Vyatīpāta* is only approximate: cf. नानायने व्यतीपातः etc.,

In the *Pauliśa Siddhānta*[2] of Varāhamihira's *Pañcasiddhāntikā* only two Mahāpātas, the *Vyatīpāta*, and the *Sārpamastaka* (also called *Vyatīpāta*), forming the 17th of the Twenty-seven Yogas are given, as also the 27th Yoga *Vaidhṛta*:

[3]विपरीतायनयातो यदार्ककाष्ठां शशी सविक्षेपः ।
भवति तदा व्यतिपातो दिनकृत्तच्छशियोगचक्रार्धे ॥ (III. 22)
अर्केन्दुयोगचक्रे वैधृतमुक्तं दशार्क्षसहितेषु ।
यदि चक्रो व्यतिपातः वेलाम्रुग्यास्थितैर्भागैः ॥ (III. 20)

It must be noted that the Sārpamastaka is a relic of the ancient times and is only the ancient *Vyatīpāta* handed down by historical

---

1. It is to be noted that yoga equal to 12 Rāśis from Winter Solstice is the same as yoga equal to 6 Rāsis from the Vernal Equinox, which is given in the usual definition of the *Vyatīpāta*.

2. In the other three Siddhāntas, *Romaka*, *Vāsiṣṭha* and the *Saura* of the *Pañcasiddhāntikā*, the *Mahāpātas* or other *Yogas* are not mentioned.

3. I am giving practically the Ms. reading in Thibaut's edn. and not the emended version of Thibaut which has spoiled the text.

continuity, as can be seen from the common name Vyatīpāta and from its being the 17th *Yoga*. For, the Sun reckoned from Śraviṣṭhā plus the Moon reckoned from Śraviṣṭhā (when equal to 12 Rāśis) gives the Vyatīpāta; *i.e.* the Sun reckoned from (Aśvinī + 5 nakṣatras) plus the Moon reckoned from (Aśvinī + 5nakṣatras) gives the *Vyatīpāta*, *i.e.* Sun plus Moon plus 10 nakṣatras gives the *Vyatīpāta*, and this result is mentioned here. It is noteworthy that Varāha does not give the set of Twenty-seven *Yogas*, Viṣkambha etc. and he does not take them up in his *Bṛhat-Saṁhitā* for astrological treatment, though he takes up even the *Karaṇa* for this purpose. He has not also given the Mahāpāta, *Vaidhṛta*, corresponding to the *Vyatīpata* given in the *Pauliśa Siddhānta*, III. 22., the given Vaidhṛta being only the ordinary 27th Yoga.

Just as Varāha gives two of the set of Twenty-seven Yogas, Prabhākara mentioned above gives seven, calling them *Sapta Mahadoṣas* :

सूर्येन्दुयोगनक्षत्रे रूपवस्वर्कपञ्चभिः ।
अत्यष्ट्या चैव धृत्या च पङ्क्तया युक्त्वा पृथक् पृथक् ॥

निरोधं परिघं वज्रं दण्डं ख(? ग)ण्डं च चू(? शू)लकम् ।
व्यतीपातं च सप्तैतान् महादोषान् विदुः क्रमात् ॥

(Quoted by Śaṅkaranārāyaṇa in his *Laghubhāskarīya-vyākhyā* under II. 29)

Among these seven, all excepting two, *nirōdha* and *daṇḍa*, can be identified by their names among the Twenty-seven *Yogas*. *Vaidhṛti*, the 27th is not mentioned. It is in the *Brahmasphuṭa Siddhānta* and the *Sūrya*, *Soma*, *Brahma*, *Vṛddha-Vāsiṣṭha* and the later Siddhāntas that the three Mahāpātas, as also the set of Twenty-seven Yogas are mentioned fully. Thus these seem to have been evolved from the simple *Vyatīpāta* of the old *Paitāmaha Siddhānta* and its contemporaries. That this is so is indicated by the term *Vyatīpāta* being used as a generic name as well, for all the *Mahāpātas* and all the baneful *Yogas*. For instance the *Sūrya Siddhānta* says: व्यतीपातः प्रसिद्धोऽयं संज्ञाभेदेन वैधृतिः (XI. 4); सप्तदशान्तोऽन्यो व्यतीपातस्तृतीयकः (XI. 20); व्यतीपातत्रयं घोरं (*i.e. Vyatīpāta*, *Vaidhṛti* and *Sārpamastaka*) (XI. 22); and Śaṅkaranārāyaṇa in his *Laghubhāskarīyavyākhyā*, under II. 29, says: अपि च व्यतीपाता बहुधा बहवः श्रूयन्ते । किं व्यतीपाताश्च तथा बहवस्सन्ति, आहोस्वित् तत्सदृशगुणदोषा एते । अत्र वयमपि न

विदुः (? विज्ञः)। तद्विदः प्रष्टव्याः। आर्यभटप्रणीतव्यतीपातावुभावेव। अन्ये दशव्यतीपातान् वदन्ति। एके पुनः सप्तमहादेषेषु विष्कम्भादिषु च धूपादिषु च व्यतीपाताः श्रूयन्ते। तेषामपि व्यतीपातदोषफलत्वात् तन्नामसंज्ञा विधीयते॥

Wrong use of Versine (Utkramajyā)

In Ch. V in the graphical representation of the eclipses (and similar matters) the directions with references to the ecliptic have to be converted into directions with reference to the observer by the application of the two corrections, *Akṣa valana* and *Ayana valana.* Here the Versine is wrongly used (cf. V. 42-47), which seems to have been a practice of the earlier astronomers and which is condemned by Bhāskarācārya II (see Editor's note under V. 46-47).

Wrong correction for Parallax

In V. 68-70 the correction for Parallax is asked to be done in the case of the lunar eclipse also, though this is really purposeless and born of a misconception. (For details see *Summary of Contents*, V. 68-70 and Note (i) thereon).

Ayana Dṛkkarma

In the Ayana Dṛkkarma (Reduction for observation depending on the ecliptic position of the planet) (Ch. VI. 1–4) the Versine is asked to be used according to the practice of earlier astronomers, which is wrong and criticised by Bhāskarācārya II (See *Summary of Contents* and Note (i) thereon).

Latitude of the Star Planets

The method given for the computation of the latitude of the Star Planets (VI. 52-55) is defective. While in the case of Mars, Jupiter and Saturn, their nodes are to be deducted from their mean longitude as corrected by their Equation of the Centre, to find the Argument of latitude, the nodes are asked to be deducted from their true longitudes. This would be proper if the nodes are previously corrected by the Equation of Conjunction got in the fourth operation. This correction of the node is given by the *Sūrya Siddhānta, Brahmasphuṭa Siddhānta* etc. and then we are asked to deduct this corrected node from the true Mars, Jupiter and Saturn. Cf. the *Sūrya Siddhānta*, II. 56-57 :

कुजार्किगुरुपातानां ग्रहवच्छीघ्रजं फलम्।
स्वपातोनाद् ग्रहाज्जीवा

In so far as this correction of the node is not given, the text is defective.

In the case of Mercury and Venus the Equation of the Centre must be applied to their Śīghra (which is their mean longitude according to modern astronomy) and then the node is to be deducted to get the argument of latitude. But in our text the application of the Equation of the Centre is omitted. This omission would be proper if the Equation of the Centre is applied to the node with its sign reversed, as mentioned in the *Sūrya Siddhānta* etc. *Cf.*

वामं (पाते) तृतीयकं मान्दं बुधभार्गवयोः फलम् ॥
स्वपातोनाद् ग्रहात् जीवा शीघ्राद् भृगुजसौम्ययोः ।

Sūrya Siddhānta II, 56-57

But this correction for the node also has not been given in the *Mahābhāskarīya* and to this extent it is defective. (See *Summary of Contents*, VI. 52-55, and Note thereunder).

The Astronmical Constants

The astronomical constants given in VII. 1-16 and 20 naturally differ from those of other schools. The constants are given below in the form of a table, with those of certain other schools, for the sake of comparison :

	Āryabhaṭīya, Mahābhāskarīya and Laghubhāskarīya	Ārdharātrika system of Āryabhaṭa, Khaṇḍa-Khādyaka, Saura-Siddhānta of the Pañca S. and the Pauliśa Siddhānta quoted by Bhaṭṭotpala in his com. on Bṛhat Samhitā	Later Sūrya, Soma, Brahma and Vṛddha-Vāsiṣṭha Siddhāntas	Paitāmaha Siddhānta of the Viṣṇudharmottara, Brahmasphuṭa Siddhānta and Siddhānta Śiromaṇi
Number of revolutions per yuga				
Sun	43,20,000	43,20,000	43,20,000	43,20,000
Moon	5,77,53,336	5,77,53,336	5,77,53,336	5,77,53,300
Mars	22,96,824	22,96,824	22,96,832	22,96,828·5
Mercury	1,79,37,020	1,79,37,000	1,79,37,060	1,79,36,999·0
Jupiter	3,64,224	3,64,220	3,64,220	3,64,226·5
Venus	70,22,388	70,22,388	70,22,376	70,22,389·5
Saturn	1,46,564	1,46,546	1,46,568	1,46,567·3
Higher Apsis	4,88,219	4,88,219	4,88,203	4,88,105·9

Jupiter	1	2 (? 100′)	1	76'
Venus	2	2	2	136'
Saturn	2	2	2	130'

Motion of Apses and Nodes

Following the *Āryabhaṭīya*, Bhāskara gives the Higher Apses (*Mandocca*) and Nodes (*Pāta*) of the planets as fixed, without giving any rates of motion for them, except, of course, in the case of the Apsis and Node of the Moon. But he says in his *Āryabhaṭīya Bhāṣya*

* Column's 3 and 4 are for circa 500 A.D.

‡ In column 1 the degrees are given after division by 4½.

that Āryabhaṭa knew of their motions and also their rates of motion but did not give them in the *Āryabhaṭīya* because the rates were extremely slow. And he points out that though Āryabhaṭa has not given them in his main work, he has given them in the form of loose verses *(muktaka)* which Bhāskara quotes in his *Bhāṣya* under *Gītikā* 9 (pp. 43-47 and p. 173). *Cf.* मुक्तककथितं किलाचार्येण –

'एक-द्वि-त्रि-चतु-रिषून् क्रमशो भगणान् प्रयान्ति सर्वेषाम् ।
कल्पादेर्गतकालान् गणनीयमतो गतिस्तेषाम् ॥' (p. 44);

and again, अथ किमिति मन्दोच्चगतिर्नाभिहिता ?........अपि च मुक्तकेनैव आचार्येण अभिहितमिति संप्रदायाविच्छेदादवधार्यते । अत्यन्तसूक्ष्मत्वात् वर्षगणेनैव आचार्येण यदाख्यातं तदेवाप्यविच्छिन्नसंप्रदायप्रतिपत्त्याभिधीयते । तद्यथा—

अष्टि-कृता-त्यष्टि-नवा-जे(?)-रुच्चयुगं तिग्मदीधितेरुक्तम् ।
दशगणगुणितैरब्दैर्विंश्वान् भुङ्क्ते क्रमाद् भगणान् ॥ (p. 46)

यथा पितुः शास्त्रसंप्रदायाविच्छित्तिकथने ग्रहपातेषूक्तं तदत्राप्यवधारणीयमिति" (p. 47).

Sin θ without Tabular sines

To Bhāskara goes the credit of giving for the first time a method to do computations without the use of the Table of sines, which he gives in VII. 17-19. This is the method he gives :[1]

$$\text{Sin } \theta = d(180^0 - d) \div \tfrac{1}{4}\,[40500 - d(180^o - d)]$$

Where d is θ, $180^0 - \theta$, $\theta - 180^0$ and $360^0 - \theta$, when θ lies in the four quadrants respectively. For a simple algebraic approximation to a transcendental function, this formula is surprisingly accurate as the following table will show.

Angle in degrees	Sine according to this formula	Actual Sine	Angle in degrees	Sine according to this formula	Actual Sine
0	0	0	45	·706	·707
3¾	·066	·065	50	·765	·766
5	·088	·087	60	·865	·866
10	·175	·174	70	·939	·940
20	·343	·342	80	·985	·985
30	·500	·500	90	1·000	1·000
40	·642	·643			

1. Brahmagupta too gives the same formula, *Cf. Brahmasphuṭa Siddhānta, Sphuṭagatyuttarādhyāya*, 23—24.

The Ārdharātrika system and its Constants

In VII. 21-35 Bhāskara describes the Ārdharātrika system[1] of Āryabhata. This system should have comprised an independent work of Āryabhaṭa, which is unfortunately not available now. From references in other works scholars have surmised that Āryabhata must have written such a work. Thus Brahmagupta begins his *Khaṇḍa-Khādyaka* saying: वक्ष्यामि खण्डखाद्यकमाचार्यार्यभटतुल्यफलम् ; but it does not agree with the present *Āryabhaṭīya*, which, therefore, presupposes another work of Āryabhaṭa. Varāhamihira says this explicitly in his *Pañcasiddhāntikā*, XV. 20 :—

लङ्कार्धरात्रसमये दिनप्रवृत्तिं जगाद चार्यभटः ।
भूयः स एव सूर्योदयात्प्रभृत्याह लङ्कायाम् ॥

Brahmagupta too says in the *Brahmasphuṭa Siddhānta*, XI. 13-14 :

अधिकैः शतैश्चतुर्भिर्वर्षसहस्रैश्चतुर्दशभिरेकः ।
युगयातैर्दिनवारान्तरमौदयिकार्धरात्रिकयोः ।
औदयिकाद्दिनभुक्तेस्तुर्यांशेनार्धरात्रिको भवत्यूनः ।
कतरं स्फुटं न निश्चितमनयोः स्फुटमेकमपि नाऽतः ॥

The *Saura Siddhānta* of the *Pañcasiddhāntikā* the *Pauliśa Siddhānta* so far as it is quoted by Bhaṭṭotpala in his commentary on the *Bṛhat Saṁhitā*, (and probably the whole of it), and of course the *Khaṇḍakhādyaka*, all agree with the Ārdharātrika system of Āryabhaṭa given here not only in the constants but also in the methods.[2] The *kṣepas* of the *Saura Siddhānta* are all derivable from the constants of this system. Strangely enough the later *Sūrya Siddhānta* constants

---

1. In the Ārdharātrika system the reckoning of days begins from midnight *(ardha-rātra)*, while in the Audayika system it begins from sunrise *(udaya)*. As at any moment during the time of Āryabhata both systems must give the same mean longitudes etc., the cycles or yuga-days must both necessarily differ in the two systems; and there are also other differences.

2. In the method of computing the latitude of the star-planets alone there seems to be lack of complete agreement. But this may be due to our not properly understanding the method enunciated ; see below.

agree with these constants only in part, which means it disagrees with the *Saura* in places other than these; (see the comparative table given above).

As the name indicates, the beginning of the *Yuga* in this system is from midnight (at Laṅkā or Ujjain meridian) as opposed to the *Yuga* at sunrise in the Audayika system. So the days from epoch (*ahargaṇa*) of the Ārdharātrika system will be greater than that of the Audayika system by a quarter of a day. The extra motion of the planets during this quarter day in the Ārdharātrika system is just compensated at the time of Āryabhata (Kali 3600) by the defect in motion due to the extra 300 days given for the *Yuga* by the system, so that except in the case of Mercury and Jupiter (where Āryabhaṭa intends different results for the two systems in his own time, and therefore gives different number of cycles per *Yuga*) the Sun, Moon etc. of the two systems agree at the time of Āryabhaṭa. Probably it is for the sake of this agreement that this system has 300 days more for the Yuga (see Table). But it must be noted that the agreement would be only for Āryabhaṭa's time and for other times the two systems would be incompatible with each other. This is why Brahmagupta accuses Āryabhaṭa of inconsistency; see Brahmagupta's quotation (XI. 13-11 above.) .Astronomers of the Āryabhaṭan school like Govindasvāmin, however, say that there is no inconsistency because the Ārdharātrika system is intended only to be examined and discarded as incorrect, in order to instil greater faith in the Audayika system. (cf. Govindasvāmin's *Bhāṣya*, end of ch. VII).

The Computation of Latitude in the Ārdharātrika system

There is a peculiarity in the method of computing the latitude of the Star-planets in the Ārdharātrika system. Two *Pātas* (Ascending Nodes) are given for each planet, the *Manda-pāta* and the *Śighrapāta*, except for Mercury which has only the *Manda-pāta*. Using the two Pātas two latitudes are got for each planet, and these two are combined to form the true latitude of the planet. In the *Saura* also two latitudes are given for each planet, but here Mercury too has two *Pātas*. Here, however, the use of the two *Pātas* is implicit and not explicitly stated as in the Ārdharātrika system given by Bhāskara; (for details see *Summary of Contents* on VII. 28 b-33 and the note thereon, as also *Pañcasiddhāntikā*, XVII. 13-14). In the *Khaṇḍakhādyaka* the method is that of the *Sūrya* and other

Siddhāntas, and there is no peculiarity, and as such the method is not the same as that of the Ārdharātrika.

The Yojana measure in the Ārdharātrika system

Something must be said about the measure in *yojanas* of the orbits of the planets and the diameters of their orbs which apparently differ very much in the two systems (see Table above). The greatness of the difference is due to the different lengths of the yojanas in the two systems, the Audayika yojana measure being one and a half times the Ārdharatrika yojana measure. So for the same thing, the number of yojanas given by the Ārdharātrika system would be one and a half times that given by the Audayika system. Thus the circumference of the celestial sphere (*Ākāśa-kakṣyā*) is 5,77,53,336 x 216,000 according to the Audayika system and 5,77,53,336 x 324,000 according to the Ārdharātrika, the latter being exactly one and a half times the former. The Moon's mean radius of orbit is 34,377 according to the Audayika and 51,566 according to the Ārdharātrika, exactly one and half times. The Sun's mean radius of orbit is 4,59,585 according to the former, and 6,89,358 according to the latter, which is practically one and a half times the former. To be exact it should be 6,89,378; and the *Pauliśa* and the *Sūrya Siddhāntas* give this figure explicitly and the *Brahma Siddhānta* implicitly. Either the figure 5 given is a scribal error or it is due to 3437.8 having been used as the divisor instead of the more correct tabular radius 3437.7. Anyhow, the error is only 1 in 34,000 and very negligible. The diameters of the orbs of the Sun, Moon and Earth according to the Audayika system are 4410, 315 and 1050 yojanas respectively, which expressed in the Ārdharātrika measure would be 6615, 473 and 1575. But the actual values of the Ārdharātrika system are 6480, 480 and 1600, the difference being due to the different system. It is to be noted that the *Sūrya Siddhānta* also gives the same values. The *Saura* in the *Pañcasiddhāntikā* gives only the radii of the orbits of the Sun and the Moon, and these are 16041 and 1200 yojanas, which evidently are not real but reduced values, the factor of reduction being 400/1719. The Ārdharātrika system of Āryabhaṭa given by Bhāskara is valuable as faithfully representing a system more ancient than the *Āryabhaṭīya.*

Govindasvāmin, the Bhāṣyakāra of Bhāskara

In Govindasvāmin who followed him not much later, Bhāskara has a worthy commentator. Śaṅkaranārāyaṇa, commenting on

Bhāskara's *Laghubhāskarīya* commences his work[1] paying obeisance to Govinda among other great astronomers:

आचार्यार्यभटं वराहमिहिरं श्रीमद्गुरुं भास्करम्
गोविन्दं हरिदत्तमत्र शिरसा वक्ष्ये प्रणम्य क्रमात् ॥

He also quotes from Govindasvāmin in this work.[2] Nīlakaṇṭha Somayājin, the reputed astronomer of Kerala, gives in a grahaṇa-tract of his[3] the information that Śaṅkaranārāyaṇa was Govinda's pupil. Discussing the *Śakābda-samskāra* of the *Parahita* system of astronomy and quoting two stray *āryās* of Āryabhaṭa, Nīlakaṇṭha says: तच्च लघुभास्करीयव्याख्याने शङ्करनारायणीये लिखितमस्माभिर्दृष्टम् ।[4] गोविन्दस्वामिनापि इमे भवभान्वादयो बीजसंस्कारश्लोका न दृष्टाः । निबन्धसंस्कार एक एव दृष्टः । स च गोविन्दकृतौ लिखितः ।.........गोविन्दस्वमिनि स्वर्गते पुनः तच्छिष्यः शङ्करनारायणः वाग्भावोनादित्युक्तं भटसंस्कारं लब्ध्वा महोदयपुरस्थोऽर्कग्रहणं दृष्ट्वा राज्ञे कुलशेखराय निवेदयामास । तेनायं केरलेषु प्रसारितः । And this relationship with Govinda is corroborated by Śaṅkaranārāyaṇa himself when he refers to Govinda as (his) teacher; *cf.* केनेदमार्याद्वयमुक्तमिति चेत् आचार्यैः भट्टगोविन्दैः गोविन्दकृतौ प्रणीतम् । (*ib.* p. 55).

Date of Govindasvāmin

The date of Govinda can be fixed from that of his pupil, Śaṅkaranārāyaṇa, which is clearly established from certain statements in his commentary on the *Laghubhāskarīya*. While dealing with the Śaka Era Śaṅkaranārāyaṇa says: एवं शकाब्दाः पुनरिह चन्द्ररन्ध्रमुनि (791) संख्या अस्माभिरवगताः (ib. page 4); this date is equal to A. D. 869. Later in the work, on page 65, he speaks of a solar eclipse which occurred on:

अङ्गत्र्येश्वरनन्दवेदमनु (14,49,066) भियति दिनानां गणे ।

and which he reported to King Kulaśekhara. This date corresponds to A. D. 866. From these we may fix the date of Śaṅkaranārāyaṇa as *c.* 825-875, and that of his teacher Govindasvāmin as *c.* 800–850.

---

1. Ed. *TSS.* 162.
2. *Cf. ibid. pp.* 19, 55, 95.
3. Ms. in H. H. the Maharaja's Palace Library, Trivandrum, No. 975, last folios.
4. The reference is to the quotation of these verses by Śaṅkaranārāyaṇa, ibid p. 26.

In his work Śaṅkaranārāyaṇa often refers to the Kerala King Ravivarma Kulaśekhara who reigned at Mahodayapuram (Vañci) on the West coast. Some of the examples in the work are questions posed by the King to the author; and in fact there are several passages in the work pointing to the interest taken by the King in astronomy. It is patent from these references that Śaṅkaranārāyaṇa was a resident of the above city and was a protege of the above King. The fact that Govinda's pupil belonged to Kerala, coupled with the fact that his works are found and studied only in that part of the country, may lead us to suppose that Govindasvāmin too belonged to Kerala.

Works of Govindasvāmin

Besides his *Mahābhāskariya-Bhāṣya*, Govindasvāmin has written at least three other works. A brief commentary called *Sampradāya-dīpikā* or *Prakaṭartha* on *Parāśarahorā* is one. Nīlakaṇṭha Somayāji quotes in his grahaṇa-tract cited above, a verse from the *Parāśarahorā* and elucidates: गोविन्दस्वामी च अस्य भाष्ये प्रकटार्थे पराशराभिप्रायमाह etc. Sundareśa (Sundararāja?) in his commentary on the Vākya-karaṇa (also called *Vākyapañcādhyāyī)* III. 2, prefixes a quotation from the work with the statement: पराशरहोराव्याख्याने सम्प्रदाय-दीपिकायां भगवता गोविन्दस्वामिना etc. Two manuscripts of this work are preserved in the Sarasvati Mahal Library, Tanjore, Nos. D. 11498 and 11499, the former copied from the latter. These contain only the *uttara-bhaga* of the work up to chapter 16, and the colophon to chapter 1 reads: इति पराशरहोरायां सम्प्रदायदीपिकायां गोविन्दस्वामिविरचितायां उत्तरभागे प्रकटार्थे प्रथमोऽध्यायः। A third manuscript of the work is also known in the Oriental Research Institute, Mysore, No. 3166.

Nīlakaṇṭha Somayāji refers in the same grahaṇa-tract cited above, to another astrological work of Govindasvāmin, the *Govinda-paddhati*. He says: आर्यभटकालादूर्ध्वं अब्दशतान्तरित एव वराहमिहिरकालः इति गोविन्दपद्धतौ होरासम्प्रदायकथनादवगतम् । सार्धसहस्रद्वये कल्यब्दे भगदत्तोऽभूत् । ततो गतेऽब्दशतद्वये वराहमिहिरश्च इति तद्वचनादवगम्यते । Manuscripts of this work are yet to be unearthed. The title *Govinda-paddhati* suggests that this might be an original work of the author.

Still another work of Govindasvāmin, which too is known only from quotations is what is referred to as *Govindakṛti*. Numerous

quotations from this work occur in astronomical works of Kerala authors like Śaṅkaranārāyaṇa, Nīlakaṇṭha and Nārāyaṇa, commentator on the *Līlāvatī*. All these quotations pertain to mathematics and astronomy, and it seems that this too is an original work of the author.

Govindasvāmin's Mahābhāskarīya-Bhāṣya

Govindasvāmin's *Bhāṣya* forms an elaborate elucidation of the *Mahābhāskarīya*. We have already seen that in Govinda's view the *Bhāskarīya* is only an exposition of the *Āryabhaṭīya* and therefore he quotes and explains *āryās* and *gītikās* from the *Āryabhaṭīya* so fully that only a few verses therein have been left out. In addition to explaining the *Mahābhāskarīya* text, Govinda gives also additional information which is his own, or reiterates what Bhāskara has said in his *Āryabhaṭīya-Bhāṣya*. Some of the more important topics which Govinda has dealt with in detail may be mentioned here. Under I. 4 he gives the origin of the Śaka era. Principles of the *Rule of Three* (*Trairāśika*) are explained under I. 7, and some rules for the fundamental operations with fractions under I. 23. Most of the examples on *Kuṭṭaka* under I.41-52 are from Bhāskara's *Āryabhaṭīya-Bhāṣya*, but under I.47 Govinda gives a novel method to find the *Mati*. Under III. 41 Govinda gives an extension of the methods given for the Sun in the east-west or north-south directions to the corner directions as well. Correction for parallax for sunrise is discussed under IV. 1, and the theory of planetary motions under IV.6. Govinda gives more exact tabular sines and also methods to get the sines to a high degree of approximation, together with the inverse operation of finding the exact arc from the sines under IV.22. Under V. 4, the size and shape of the earth, Sun and Moon and the planets, the position of the earth in the solar system, the rotation of the earth and rising and setting of the Sun, and the motion of planets in their orbits are discussed. Under V.7, what is meant by *Rāhu* in astronomical works is clarified, following and quoting Varāhamihira. For details see *Notes* under the respective *ślokas* in the *Summary of Contents*.

Govindasvāmin refers to a few variants of the text, and these have been noticed below where variants of the text are discussed in the section on *Manuscript Material*. Variants of the *Bhāṣya* in the different manuscripts used for this edition and those preserved in the super-commentary of Parameśvara have been noticed below under Manuscripts of the *Bhaṣya* and of the *Siddhāntadīpikā*.

Parameśvara, author of Siddhāntadīpikā

Parameśvara, author of the super-commentary on Govindasvāmin's *Bhāṣya* is one of the renowned astronomers of Kerala of the mediaeval times. His chief service to astronomy is the revision of the *Parahita* system of astronomy prevalent in Kerala, and founding his *Dṛgganita* system in order to make the results of calculations accord with observation. He came of the Bhārgava gotra and Āśvalāyana sutra, and was a resident of the village of Ālattūr (also called Vaṭaśśeri or Vaṭaśreṇi) in South Malabar. His house was situated on the northern bank of the Nilā or Bhāratappuzha river joins the sea, a fact which he mentions in several of his works: where it *Cf.* for instance the beginning verse of his *Goladīpika*[1] :

निळायाः सौम्यतीरेऽब्धेः कूलस्थः परमेश्वरः ।
संक्षेपाद् गोलसंस्थानं वक्ति बालाय भार्गवः[2] ॥

And at the end of the same work he spcifies the place by laying down its latitude and longitude :

समरेखायः पश्चादष्टादशयोजनान्तरे ग्रामे ।
स्वरकृतषट् (647) तुलिताक्षे.................... ॥ IV. 91

Thus it was 18 yojanas to the west of the central (Ujjain) meridian and having a sine latitude of 647 (corresponding to 10° 51' north latitude),

Parameśvara's Family and Teachers

Parameśvara belonged to a family of scholars in astranomy and he mentions his grand father as a student of the reputed astronomer Govinda,[3] author of *Muhūrtaratna*. Thus Parameśvara says in his commentary on this work :

गोविन्दपूज्यपादेन कृपासंसिक्तचेतसा ।
मुहूर्तागमदुग्धाब्धेः मुहूर्तमणिरुद्धृतः ॥

---

1. Ed. with Translation and the author's own commentary by K. V. Sarma, *Adyar Library Bulletin, XX* (1956), XXI (1957).

2. See also one of the concluding verses of Siddhāntadīpikā edited here : निळायाः संगमात् सौम्ये etc.

3. Obviously this Govinda is different from our Govindasvāmin.

तस्मिंस्तच्छिष्यपौत्रेण कियांश्चित्परमादिना ।
भावो विव्रियते स्वल्पमीश्वरेण यथाश्रुतम् ॥

He refers to a line of teachers and this Govinda too, in another work of his, the *Ācārasaṅgraha ; Cf.*

पितुः पितुर्मे गुरुरग्रजन्मा गोविन्दनामा भुवि विश्रुतोऽयम् ।
तेनोदितो यो गुरुपंक्तितो मां प्राप्तः स आचार इह प्रदिष्टः ॥

Parameśvara mentions his teacher Rudra in several of his works. The introductory verse to his *Vākyakaraṇa* runs :

पूज्यपादस्य रुद्रस्य शिष्योऽयं परमेश्वरः ।
करोति वाक्यकरणं वाक्यावयवसिद्धये ॥[1]

While he was young, Parameśvara studied also under a Mādhava and a Nārāyaṇa, and this is stated by Nīlakaṇṭha Somayāji in his *Āryabhaṭīya-Bhāṣya, Gola.* 48 : परमेश्वरस्तु रुद्र-परमेश्वरात्मजनारायण-माधवादिभ्यो गोलविद्भ्यो गणितगोलयुक्तीरपि बाल्य एव सम्यग् गृहीत्वा etc.

Parameśvara's Date

At least in two of his works Parameśvara gives the dates of their composition. His *Goladipikā* was composed in A.D. 1443 (Śaka 1365) *cf.* शाकेऽक्षषट्त्रिचन्द्र(1365)मिते ।
परमेश्वरनाम्नेयं वदनभुवा गोलदीपिका रचिता ॥ IV. 91-92

and his *Dṛggaṇita* was written twelve years earlier in A.D. 1431 (Śaka 1353); *cf.* एवं दृग्गणितं शाके श्रीगुविश्व(1353)मिते कृतम् । Nīlakaṇṭha Somayāji states in his *Āryabhaṭīya-Bhāṣya, Gola.* 48, that the latter work was the result of 55 years study of the heavens : *cf.* परमेश्वरस्तु......क्रियमाणप्रयोगस्य दृग्विसंवादं तत्कारणं चावधार्य, शास्त्राण्यपि बहून्यालोच्य, पञ्चपञ्चाशद्वर्षकालं निरीक्ष्य ग्रहणग्रहयोगादिषु परीक्ष्य सम-दृग्गणितं करणं चकार । A little further down in the same context Nilakantha quotes Parameśvara's own words :—

ग्रहेन्द्राः पञ्चपञ्चाशद्वर्षकालं निरीक्षिताः ।
मया, तदा दृशा भिन्ना दृष्टाः परहितोदिताः ॥
उदाहरणमप्यत्र किञ्चिदेषां विलिख्यते ॥

---

1. See also end of *Siddhantadipika* edited here, व्याख्या तस्य मया कृता लघुतरा रुद्रप्रसादादिति ।

Therefore deducting 55 years from 1431, the date of composition of *Dṛggaṇita*, will take us to the time from when Parameśvara began to scan the heavens, viz. *C.* 1376; and we may not be wrong in taking as his date of birth *C.* 1360.

The upper limit to Parameśvara's date is also supplied by Nīlakaṇṭha Somayāji (born 1443 A. D.)[1] who was a regular pupil of Dāmodara son of our Parameśvara. At one place in his *Āryabhaṭīya Bhāṣya, Gola.* 48, Nīlakaṇṭha says that Parameśvara, his grand teacher (*Paramācārya)*, explained to him certain points on astronomy. Thus speaking about the Higher Apsis of Mars he says:

तच्च श्रीपतिमुञ्जालसूर्यदेवादिसम्मतम् ।
तदेव परमाचार्यो ममाह परमेश्वरः ॥

This would imply Parameśvara being alive during Nīlakaṇṭha's younger days, and we may therefore place his last days about 1460. Parameśvara thus flourished between 1360 and 1460 A.D.

Works of Parameśvara

A prolific writer, Parameśvara's writings cover both astronomy and astrology, and besides original treatises he has commented upon several classical works on these subjects. His works on astronomy are: *Dṛggaṇita* presenting the fundamentals of his revision of the *Parahita* system of astronomy; two *Goladīpikās* and his own commentary on one of them (Ed. respectively in *TSS* 49 and *Adyar Library Bulletin*, XX-XXI, 1956-57) on the theories and conceptions of spherical astronomy; three works on eclipses, the short *Grahaṇāṣṭaka* and the longer *Grahaṇamaṇḍana* and *Grahaṇa-nyāyadīpikā*, and *Vākyakaraṇa* on the method of derivation of the *vākyas* of several astronomical tables.

Of Parameśvara's commentaries may be noted: *Bhaṭadīpikā* on the *Āryabhaṭīya* (Ed. Kern, Leiden, 1874); *Karmadīpikā* on the *Mahābhāskarīya* (*AnSS* 126, Poona, 1945); *Siddhāntadīpikā* on the *Mahābhāskarīya-Bhāṣya* (edited here), *Pārameśvara* on the *Laghu-bhāskarīya* (*AnSS* 128, Poona, 1946) and on the *Laghumānasa* of Muñjāla (*AnSS* 123, Poona, 1944), *Vivaraṇa* on the *Sūryasiddhānta* and on *Bhāskarācārya* II's *Līlāvatī*; and a *Vṛtti* in verse on *Vyatīpātāṣṭaka*.

---

1. *Cf.* Introduction to the *Siddhāntadarpaṇam* of Nīlakaṇṭha, Ed. K. V. Sarma, Adyar Library, Madras, 1954.

Parameśvara's contributions to the astrological bronch of Jyotiṣa are the two original treatises, *Ācārasaṅgraha* and *Jātakapaddhati*, and commentaries on the *Muhūrtaratna* of Govinda, *Jātakapaddhati* of Śrīpati and *Praśnaṣṭapañcāśikā* of Pṛthuyaśas[1].

In one of the concluding verses to his commentary on the *Mahābhāskarīya*, Parameśvara recounts a list of some of his works: *Cf.*

मुहूर्ताष्टक-सिद्धान्त-वाक्य-भा-न्याय-कर्मणाम् ।
दीपिकां गोल-भट्योश्चाकरोत् परमेश्वरः ॥

Of these, manuscripts of three works, *Muhūrtāṣṭakadīpikā*, *Vākyadīpikā* and *Bhādīpikā* are yet to be discovered. Besides these, there are some other works which are likely to be by our author, but which require confirmative evidence of his authorship.

Parameśvara's work was continued by his son Dāmodara, the latter's pupil Nīlakaṇṭha Somayāji, and a line of astronomers following him. And the *Dṛggaṇita* mode of astronomical computation enunciated by him has been very popular in Kerala ever since.

Parameśvara's Sidddhāntadīpikā

The *Siddhāntadīpikā* of Parameśvara edited here though expressedly a commentary on Govindasvāmin's *Bhāṣya* on the Mahābhāskarīya, is often more than that and takes up the role of the *Bhāṣya* itself where the latter is sparse, and comments on the original text itself. Besides, in several places it gives original ideas and methods of its own, in great detail, mostly in metrical form. These excursions may be pointed below.

Under I.41 the principle and method of reduction of fractions used in the solution of Indeterminate Equations is elaborated. The Siddhāntadīpikā gives its own method of finding the *Mati* under I.47, and under I.52 it quotes an alternate method to solve equations of the type called *Sāgra-Kuṭṭākāra*. Under III. 22 it gives an alternative interpretation of III. 21-22 as given by 'certain astronomers' (*anye punaḥ*), and under III. 39, an amplification of the process of getting the interval between the Sun

---

1. For details of manuscripts of these unpublished works see K. V. Sarma, Introduction to his edition of Parameśvarā's *Goladīpikā*, *Adyar Library Bulletin*, XX, 1956.

on the Prime vertical and the midday, in 24 verses. For the *Bhāṣya* example '*chāyā raver narasamā*' under III. 41, the commentary gives an alternate method in 11 *ślokas*. Under the same verse it gives also a method to solve problems with the Sun at the intermediate directions, alternative to what is given in the Bhāṣya, and also extending it to the Sun in any direction. Under III. 54 it explains the principle involved in the method of drawing a circle passing through three points. There is a long discursion in 68 *ślokas* giving an alternate method to obtain exact sines and arcs, under IV. 22. Parameśvara gives under IV. 54 the opinion of certain astronomers in the matter of making the correction for the Equation of the Centre and for the Equation of Conjunction; and after that he gives instructions for graphical representation of the Ex-centric and Epicyclic methods in 32 stanzas. Under V. 39b, a possible error in the text is sought to be rectified. The long excursion at the end of V in about a hundred *ślokas* is a regular treatise on the theory of eclipses with a detailed description of Parameśvara's own observations of several solar and lunar eclipes from which important astronomical data can be derived. Under VI. 29-31 the *Siddānta-dīpikā* gives an alternative interpretation of the verses as given by 'certain astronomers' and the different methods given by them. Under VI. 55 it shows an awareness of the error in the method given in the text for computing the Latitudes of the Star-planets. Under VII. 28b-33 the interpretation of the method of computing the Latitude of the Star-planets according to the *Ārdharātrika* system given by Parameśvara is probably wrong in certain details. (For details see *Summary of Contents* and also *Introduction, supra* page XLV ff.)

Besides these valuable additions and corrections, the *Siddhānta-dīpikā* discusses alternative readings both of the text and the Bhāṣya, and these are indicated below under *Manuscript Material*.

MANUSCRIPT MATERIAL

Manuscripts of the Text

The present edition of the Text of *Mahābhāskarīya* is based on the following eight palm-leaf manuscripts designated *A* to *H*, seven written in Malayalam script, and one, *G*, in Grantha script; collation of two of the former, (*C* and *H*), was done from modern paper transcripts prepared from them.

A. Ms. No. 475-B of the Travancore University Manuscripts Library, Trivandrum, an old Ms. procured from the Kūṭallūr Mana in South Malabar. The Ms. is much worn out and is fragile to the touch. The original owner and scribe of the Ms., as stated in the Ms. itself on ff. 33^b and 99^a, was Nīlakaṇṭha of the Vaṭaśreṇi family, probably the family of Parameśvara himself. The date of it's transcription given on *f*. 7^b in the Kali chronogram सेव्यो दुग्धाब्धितल्पः (16,99,817) works out to A. D. 1552. The Ms. is thus more than 400 years old. The codex contains about fifteen works, all on astronomy. The text preserved herein is generally pure and free from scribal or other errors.

B. Ms. No. 5847 of the above Library, containing both the Text and the Bhāṣya. The text herein closely follows the Bhāṣya. The Ms. is not free from scribal errors and occasional lacunae.

C. Ms. No. R. 5138 of the Government Oriental Manuscripts Library, Madras, a modern transcript of the Text and the Bhāṣya in Grantha script, prepared from a Malayalam palm-leaf original. This Ms. too is not free from scribal errors and some lacunae.

D. Ms. No. 945 of H. H. the Maharaja's Palace Library, Trivandrum, containing both the Text and the *Bhāṣya*. This Ms. is, however, fragmentary, extending only through 16 verses of Ch. I. The text preserved is generally free from errors.

E. Ms. No. 977 of the above Palace Library. This Ms. also contains both the Text and the *Bhāṣya*. This too is incomplete, extending from III. 23 to the end of chapter V. The text preserved is comparatively pure and free from errors.

F. Ms. No. 8324-A of the Travancore University Manuscripts Library, contained in a codex of nine works, all on astronomy. The Ms. is old and damaged. Scribal errors are not infrequent herein.

G. Ms. No. 902 of the Palace Library, Trivandrum, containing Chapters I to V. This is a Ms. in Grantha script. The text contained is generally pure and error-free.

H. Ms. No. D. 13465 of the Government Oriental Manuscripts Library, Madras, a paper transcript in Devanagari script prepared from a Malayalam original in palm-leaf. This Ms. is, however,

vitiated by numerous scribal errors and is far from trustworthy; obvious errors and corruptions from this Ms. are not recorded in the footnotes.

Mutual relation of the Manuscripts of the Text

The above eight manuscripts do not range under definite groups (except *B* and *C*), and each has some unique readings of its own as can be seen from the variants recorded in the footnotes.

Thus *A* differs from all in III. 30, 35, 36; IV. 10, 21 etc., but shows a special alignment with *F* in some places (*cf.* I. 41, 45, 71-72; VI. 3, 5, 15, 49 etc.) and the two have in common omissions of some verses (*cf.* VI. 4a, 35, 36; VIII. 27b), as also a common extra verse VI. 59, not found in *B, C, H. Ms.* *F* has however some common readings with *G* and *H* (*cf.* III. 46; IV. 6 etc.) which are not found in *A*.

Manuscripts *B* and *C* generally go together in the matter of readings, corruptions and even gaps (*cf.* VI. 41), and must have been derived from a common original; there are, however, small differences between these two, which would indicate that this derivation from a common original is not immediate.

E has some common readings with *B* and *C* (*cf.* III. 41; V. 65 etc.), and *F* with *G* and *H* (*cf.* III. 46; IV. 6 etc.) against the other Manuscripts. Manuscsipts *F* and *H* have two extra verses after VIII. 22 which seem to be interpolations (see post-colophon note in *F*).

Manuscripts *G* and *H* are each peculiar by themselves though they have many common readings between themselves (*cf.* II. 3; III. 8, 9, 14, 15, 17, 26, 29, 53, 64; IV. 1, 7, 13, 21, 43, 60; V. 3,4, 16, 23 etc. and the common transposition of verse III. 45 two verse above).

H in spite of its numerous scribal errors, preserves several readings peculiar to itself: (*cf.* I. 3, 6, 15, 37; II. 4; III. 15, 65, 74; IV. 6, 12, 21, 24, 45; V. 2, 40, 71; VI. 3, 12, 39, 46, 49, 50, 52, etc.); again it alone omits the verses I. 12: V. 18, 26, 27^a, 47, 48^a, 52^b and 59.

G, which is a palmleaf manuscript in Grantha script, varies in a number of places from all the others which are in Malayalam[1], the

---

1. *Cf.* I. 29, 38; II. 6; III. 4, 12, 14, 27, 28, 30, 38, 39, 51, 55, 57, 64, 68, 73, 74; IV. 10, 14, 19, 20, 31, 34, 38, 44, 46; V. 2, 13, 29, 34, 35, 37, 42, 43, 46

variance often extending to a quarter or sometimes even to half a verse (*cf.* I. 38; II. 6; III. 64, 68, 74; IV. 10, 14, 19, 31, 38, 46; V. 2, 10-11, 34, 42, 46, etc.). In this M̄s. alone are verses V. 31 and 32^a omitted; it also transposes I. 48 to after I. 51.

Variants pointed out in the Bhāṣya and Siddhāntadīpikā

Apart from the variants preserved in the Text Mss., attention may be drawn to a few but significant variants noted by Govindasvāmin and Parameśvara. The Bhāṣya notes a variant in I.8 अन्ये पुनरन्यथा पठन्ति—'यदीरितान्' इति; and in I. 43, स्वशेषमिति वा पाठो द्रष्टव्यः which are not recorded in any of the Text Mss. But a third reading which it has in II. 3, स्वाक्षांशान् for अक्षांशान्, is found in *G* and *H*.

Variants of the Text pointed out by Parameśvara are not many, but some are noteworthy. Besides noting mere variants (*cf.* I. 47; II. 9; III. 17, 46) he sometimes points out the proper order of the verses (*cf.* V. 66-67), or quotes the full verse where necessary (*cf.* V. 45; VIII. 5; see especially the former, where all Text manuscripts except *A* and *F* read the verse substantially different). In III. 8 he points out a lack of accuracy and gives a variant version of the entire verse as adopted by "others": अतः कैश्चिदेवं पठ्यते—वसुत्रिदस्रा etc. Where different readings exist, he points out the सुपाठः (*cf.* IV. 15). In V. 43 Parameśvara criticises the accuracy of the text and himself suggests an emendation to rectify the defect. The critical outlook of Parameśvara is evident when he says in V. 42-43: अत्र लेखकदोषात् केषुचित् पुस्तकेषु पाठक्रमस्य व्यत्यासो दृश्यते। अतः पाठक्रमश्च कुत्रिचिद् विलिख्यते, and quotes the full verses giving the correct text. It appears that the manuscript of the Text of *Mahābhāskarīya* used by Parameśvara accorded with our manuscripts *F* and *A* (which latter, as remarked before, appears to have belonged to Parameśvara's family), since some of the readings adopted in the Siddhāntadīpikā are found only in these two manuscripts; *cf.* for instance: IV. 15 समे for विषमे; IV. 43 दिशौ for दिशा and स्फुटा; IV. 45 whole verse; and VI. 59 whole verse.

Manuscripts of the Bhāṣya

The edition of Govindaśvāmin's *Bhāṣya* is based on the following five Malayalam plam-leaf manuscripts *A* to

E,[1] one of them, *C*, being a modern paper transcript in Grantha script from its Malayalam original.

A. Ms. No. 903 of H. H. the Maharaja's Palace Library, Trivandrum. This is an old but well-preserved Ms. about 475 years old, its date of transcription, Kali year 4580 corresponding to A. D. 1478, being given in a post-colophon verse :

कलिसमासु वियद्विषभृत्पुर्विषयवेद (4580) सितासु वृषं गते ।
वृषगुरौ वृषकेतुनिषेविणा द्विजवृषेण समुल्लिखितो ह्ययम् ॥

The scribe is a great devotee of Śiva, as is seen from the above verse and a second post-colophon verse below :

किं विधुना किं मधुना किं सुधया किं च वसुधयाखिलया ।
शिव शिव शिव शिव शिव शिव शिव शिव शिवेति संलपताम् ॥

The text preserved in this Ms. is generally pure and free from errors.

B. Ms. No. 5347 belonging to the Travancore University Manuscripts Library, Trivandrum. The Ms. is well-preserved and the writing is very legible. The text preserved is, however, not very pure. It contains also the text of *Mahābhāskarīya* (Text Ms. *B*).

C. Ms. No. R. 5138 of the Govt. Or. Mss. Library, Madras. A Grantha transcript on paper from a Malayalam Ms. The *Bhāṣya* herein too is not free from errors. The Text is also available in this Ms. (Text Ms. *C*).

D. Ms. No. 945 of the Palace Library, Trivandrum. This is a fragment containing text manuscript *D* and the Bhāṣya extending from the beginning up to I. 16. It is written on sixteen folios at the beginning of a codex containing Udayadivākara's commentary on *Laghubhāskarīya*, and hence is left out from being separately catalogued in the Library's Catalogue.

---

1. One other Ms. of the *Bhāṣya* which was available in the Travancore University Oriental Manuscripts Library, No. L. 1397, could not be used since it was returned to its owner, the Raja of Koṭṭappaṭi, South Malabar, and efforts to procure it from the Raja were not successful.

E. Ms. No. 977 of the above Palace Library. This Ms. is incomplete and extends from III. 23 to the end of V. The text is also contained herein (Text Ms. *E*). This is written on folios 59 to 98 of a Ms. of Udayadivākara's commentary on *Laghubhāskarīya*, and is therefore, left out from being separately catalogued in the Library's Catalogue. The Ms. is in good preservation and is generally free from scribal or other errors.

Mutual relation of the Bhāṣya Manuscripts

Of the *Bhāṣya* Mss. *A* stands on a footing different from all the others, which latter generally align together. It also seems that the *Bhāṣya* Ms. before Parameśvara accorded with *A* as certain variant readings definitely show: Thus in IV. 61 (p. 243) this Ms. has a haplographical omission and the *Siddhāntadīpikā comments on this lacunal Bhāṣya*. Again Parameśvara discusses the propriety of a *Bhāṣya* passage under the same verse (p. 246) and the reading justified by him is that of *A* against *B. C. E.* Similarly under IV. 7 (p. 186), Parameśvara adopts and discusses the *A* reading यतो भचक्रादि etc. and later explains the *B. C. E.* reading यतो न भचक्रादि as an alternative reading. Again under V. 4 (p. 259) he explains the *A* reading गतित्वात् as against *B. C. E.* reading. Of *B. C. E.*, *B* and *C* are closely related even as to presume their derivation from the same original, though not immediately. *E*, available only for Chapters III-V, though belonging to the above group, preserves a more correct text and does not have the several scribal errors and lacunae from which *B* and *C* suffer. A few gaps are found common to all the three manuscripts (*cf*. pp. 25, 70, 267, 305, 314, 387) which should have descended from the common archetype of these manuscripts.

Manuscripts of Siddhāntadīpikā

Only two manuscripts of Parameśvara's *Siddhāntadīpikā* could be obtained for the use of this edition. They are:

A. Ms. No. 274 of the Travancore Univ. Mss. Library, a well-written, complete palm-leaf Ms. in Malayalam script. The Ms. is old and the fringes are crumbling due to age. The Ms. is in two hands, and after folio 103, three extra folios are found on which is written a section of the commentary in duplicate, with some lines in a different version but with the same sense (see below pp. 322-24, footnote). The Ms. is generally correct and free form

scribal and other errors. After the colophon are written the following two extraneous verses, the second of which is left off incomplete:

निदाघपांसुस्तम्भाग्रैरचलैर्डम्बरैरपि ।
लिप्तीकृत्य ध्रुवाद्यर्का भौमादीनां भवेद्धनुः ॥

षड्गाथानिग(?ह)ता(त्) तस्माद्धरापतिह्वताः कलाः ।
पुष्पधनुष्यत्र घ..............................

B. Ms. No. T. 931 of the above Library, described in the Descriptive Catalogue of Sanskrit Manuscripts of the Curator's Office, Trivandrum, Vol. V, pp. 1744-47. This is a transcript of a palm-leaf Ms., No. 976, in the Palace Library, Trivandrum. This Ms. has some gaps in the beginning and is not entirely free from scribal errors. The last folio of the Ms. is also full of gaps and thus the following lines written after the colophon are imperfect and details about the scribe etc. given therein cannot be fully made out:

श्रीमच्छङ्करपादपङ्कजरजःपुञ्जप्रभापिञ्जर-
ग्रीवालम्बिशिरोरुहो वसुमतीगीर्वाणवृन्दारकः ।
भारद्वाजमहान्ववायतिलकः श्रीदेवयानात्मजो
गोलप्रेक्षणदर्पणं लिखितवानेत............ ॥

............नात्वय..........चापला-
न्मातृकापत्रिकाशास्त्रजादीनवाक् ।
यो लिपेरस्फुटत्वादिदोपोऽत्र सं-
त्यज्यतामाशु सुज्योतिषज्ञैर्जनैः ॥

तारकसुधाशनविनाशनमनोहरः
पीठपत..........

Mutual relation of the Siddhāntadīpikā Manuscripts

The above two manuscripts preserve a practically uniform text though they are independent of each other as indicated by small but distinct variants (*cf*. pp. 48, 56, 65, 79, 109, 146, 220, 321 etc.), additions (*cf*. pp. 247, 320), and lacunae (*cf*. pp. 4, 7, 8, 9, 10, 23, 24, 34, 53). A few common gaps occur in both the manuscripts (*e.g.* see p. 85). A significant variant may be noted here which occurs in the long discursion under V. 77 (pp. 321-333). Manuscript *A* has in this place three extra folios which contain a repetition of part of

the commentary, which has in the place of verses 9-17 of the discursion fifteen slightly different verses, giving more or less the same sense. It seems that these verses too are by Parameśvara himself and that one might be the revised version of the other.

The Text of the Bhāṣya and the Siddhāntadīpikā

As in the case of the text of the *Mahābhāskarīya*, with regard to Govindasvāmin's *Bhāṣya* also, Parameśvara offers text-criticisms and records variants. He often discusses alternate readings (*cf.* pp. 186, 188), and more frequently gives specifically the full *Bhāṣya* passages in places of difficulty or doubt (*cf.* pp. 140, 246, 263, 317, 363, 367, etc.). On rare occasions he also discusses in his commentary the propriety of statements made by the Bhāṣyakāra. (see for instance p. 303).

Parameśvara's Commentary on the Mahābhāskarīya

That Parameśvara wrote also a direct commentary called *Karmadīpikā* on the *Mahābhāskarīya* has been mentioned before.1 Parameśvara says in the introductory verses to this commentary that he wrote it after writing his commentary *Siddhāntadīpikā* on the *Mahābhāskarīya-Bhāṣya* :

व्याख्याने भास्करीयस्य भाष्यस्य प्राक् प्रदर्शिता ।
ग्रहकर्मोपपत्तिस्तु सगोला विस्तरान्मया ॥

क्रियामात्रप्रसिद्ध्यर्थमधुना मन्दचेतसाम् ।
व्याख्याल्पा तस्य मूलस्य क्रियते कर्मदीपिका ॥

This commentary, as Parameśvara himself observes, is brief and to the point, confining itself merely to the explanation of the textual verses, and avoids the long discussions and discursions which are characteristic of his commentary on the *Bhāṣya*. An edition of this commentary with the *Mahābhāskarīya* has been issued in the *Anandasrama Sanskrit Series, No.* 126 (Poona, 1945). The Text in this edition is, however, extremely corrupt, obviously having been based on defective manuscripts. It has not been possible, therefore, to make any use of the Text in this publication for our edition of the work.

---

1. See above p. LII.

Conclusion

In concluding this Introduction it is my pleasant duty to acknowledge the help I have received from various hands in my editorial work. I am indebted to the authorities of the Travancore University Manuscripts Library, and H. H. the Maharaja's Palace Library, Trivandrum, for manuscripts of the *Mahābhāskarīya*, the *Bhāṣya* and the *Siddhāntadīpikā*. My thanks are due also to the Curator of the Govt. Oriental Mss. Library, Madras, for making available to me the manuscripts in his Library and helping me in all possible ways. I record with pleasure the help and active co-operation that I received from Sri K. V. Sarma of the Sanskrit Department of the University of Madras in the collection of the large manuscript material, their collation and edition, and the passing of the work through the press. I am also indebted to Sri Sarma for his valuable suggestions in the editorial work and for supplying me with information, especially about Govindasvāmin and Parameśvara from the mass of information he has collected on Indian astronomy, Kerala astronomy in particular. My thanks are also due to the Sri Ramachandra Printing Works Madras—14, for the neat execution of the printing work. It redounds to the credit of the Government Oriental Manuscripts Library, Madras, to have brought out this edition of one of the little-known but important classics of Indian astronomy with an old *Bhāṣya* and a detailed super-commentary.

MADRAS,
Taiṣya Śukla Ekādaśī,
12th January, 1957.

T. S. KUPPANNA SASTRI

MAHABHĀSKARĪYAM

SUMMARY OF CONTENTS

CHAPTER I

In Ch. I the Mean Planets[1] and their *Sighras* are computed (stanzas 4–40) and Indeterminate analysis or Diophantine equations, called in Sanskrit *Kuttaka*, are dealt with in detail (stanzas 41–52).

1. Salutation to Śiva.

2-3. Salutation to the planets, the *Āryabhaṭīya* and the school of Āryabhaṭa.

The Calculation of the Days from Epoch

4-6. One method of calculating the *Ahargaṇa* or total days from Epoch (in this work the beginning of *Kaliyuga*) is given: Add 3179 to the Śaka years elapsed. The Kali years elapsed are got. Multiply this by 12 and add the months Caitra etc. elapsed. To this add the quotient got by multiplying this by the intercalary months in the *yuga* and dividing by the solar months in the *yuga*; we get the lunar months gone. Multiply this by 30 and add the *Tithis* elapsed, counting from the first day of the bright fortnight *(Śukla-pratipad)*. From this subtract the quotient got by multiplying this by the Avamas (*Omitted tithis*) in the yuga and dividing by the tithis in the yuga. This is the *Ahargaṇa*. Divide this by 7 and get the remainder. The week-day equal to the remainder, counting from Friday, is that of the last day of the *Ahargaṇa*.

Note 1. The day begins from mean sunrise at Ujjain meridian.

Note 2. The process presumes reckoning by the mean lunar month and the mean tithi. Since in actual practice it is the true lunar month and the true tithi that are used for reckoning, we must take into account any intercalary month that has occurred during the current year, and also add or subtract a day from the *Ahargaṇa* to agree with the week-day.

---

1. The term *Planet* used in this work refers to the Sun, the Moon, (sometimes even the Moon's Ascending Node and Moon's Apogee), Mercury, Venus, Mars, Jupiter and Saturn, the last five being sometimes termed *Star-planets (Tārā-graha)*.

Note 3. The necessary data like the intercalary months etc. are given in chapter VII.

Note 4. The commentary mentions how the *Śaka Era* came into use.

7. Another method to get the *Ahargaṇa* is given. Multiply the Kali years elapsed by 12 and add the months gone in the current year. Multiply this by the lunar months in the yuga and divide by the solar months in the yuga. Multiply the quotient by 30 and add the tithis gone. Multiply this by the civil days (*Sāvana* or *Bhū dina*) in the yuga and divide by the tithis in the yuga. The quotient is the Ahargaṇa. (This is to be checked by the week-day and one day added or subtracted if necessary.)

Note. The *Bhāṣya* here contains an explanation of the *Rule of Three* (*Trairāśika*) and its principles.

The Computation of the Mean Planets

8. If for the days in the Yuga there is the given number of revolutions of the planet (given in Ch. VII), what is the number of revolutions for the Ahargaṇa? From this proportion the planets are got. The fraction of a revolution is converted into *Rāśis* etc. by being multiplied by 12 etc.

Note. To the Higher Apsis (*Mandocca*) of the Moon got, 3 Rāśis are to be added. The Ascending Node (*Śighrocca*) got should be deducted from 6 Rāśis (*see* I. 40).

9. The Mean Sun being known, the other planets can be got thus by proportion: Multiply the Mean Sun together with the revolutions from epoch by the revolutions of the planet in the Yuga, and divide by 43,20,000, (which is the Yuga-revolutions of the Sun). The Mean Planet is got. (*Note* under 8 applies here also).

10. Any Mean planet being known together with the number of its revolutions gone from epoch, the Mean of any other planet can be found by multiplying the known Mean by the number of revolutions per yuga of the wanted planet and dividing by the number of revolutions per yuga of the known planet. (*Note* of 8 applies here too).

11-12. An easy method to find either the Sun or the Moon, when the other is given, together with the Ahargana. (i). With the Mean Sun given: Multiply the Ahargaṇa by the intercalary months per yuga and divide by the days in the yuga. The result are revolutions etc. Add to this 13 times the Mean Sun. The Mean Moon is got.

(ii). With the Mean Moon and its revolutions known: Deduct the revolutions etc. got in (i) from the revolutions etc. of the Mean Moon. Divide the remainder by 13. The Mean Sun is got.

Note. The rules are explained thus:

चन्द्रभगण – रविभगण = चान्द्रमास = रविमास + अधिमास
= 12 रविभगण + अधिमास
∴ चन्द्रभगण = 13 रविभगण + अधिमास
रविभगण = (चन्द्रभगण — अधिमास) ÷ 13

13-19. The Calculation of the Sun and the Moon without getting the Ahargana.

Multiply the Kali years gone by 12, and add the months; multiply this by 30 and add the tithis gone; this is *Saura* days gone. Multiply this by the intercalary months per yuga and divide by the Saura days in the yuga. The quotient are intercalary months gone. The remainder is called *Adhiśeṣa*. Multiply the *Adhiśeṣa* gone by 30 and add to Saura days gone. Multiply this by the *Avamas* per yuga and divide by the tithis per yuga. The remainder here is called *Avamaśeṣa*. Multiply the *Avamaśeṣa* by the intercalary months per yuga and divide by the civil days per yuga. Add the quotient to the *Adhiśeṣa*. Divide this by the Lunar months per yuga. The result are degrees etc. Call this *A*.

Multiply the *Avamaśeṣa* by 60 and divide by the civil days per yuga. The result is minutes etc. Add this to the tithis gone taken as degrees and the months gone taken as Rāśis. Call this *B*. Then (13*B*—*A*) is the Mean Moon. (*B*—*A*) is the Mean Sun.

Note. *A* is the *Adhi-tithi* upto mean sunrise. It consists of two parts, the Adhi-tithi to the end of the full tithi and the Adhi-tithi for the rest of the day till mean sunrise. *B* is the Lunar month and tithi (fraction included) upto mean sunrise. This too consists of two

parts, the Lunar months and full tithis, and the fraction of the tithi due to Avama-śeṣa, thus giving *B* upto mean sunrise. Therefore, Lunar month and tithi *minus* Adhi-tithi = Solar month and Saura day, *i.e.* (the Sun in Rāśis, degrees etc.) = *B–A*. Mean Moon = 12 × Lunar month and tithis etc. + Mean Sun = 12B + (B–A) = 13B – A.

Another method for the Mean Planets

20. Divide the *Ākāśa-kakṣyā* by the days per yuga. The result is the motion of any planet per day, in yojanas. This multiplied by the Ahargaṇa and divided by the respective planet's orbit gives the Mean planet in revolutions, Rāśis etc.

Note. The Bhāṣya here explains the rule, giving the theory of the motion of planets. It is presumed that the speed of motion of all planets is the same.

21-40. An easy method to find the Mean Planet

This is to avoid multiplication and division by large numbers.

(i) Multiply the Kali years by $11\frac{389}{6,000}$ and divide by 30. The quotient are intercalary months, and the integral remainder, Adhidina.

(ii) Multiply the Kali years by $\left(\frac{29}{36}+\frac{43}{72,000}\right)$. The quotient are "*Avamas*" and the remainder with denominator 72,000 is *Avama-śeṣa.* Divide this *Avama-śeṣa* by 1125. The quotient are "*Days*".

(iii) Deduct the Adhidina from the "*Days*". The result are the "*Tithis*" after the last Avama up to the end of Phālguna. If the Adhidina cannot be deducted, add 64 to the "*Days*" and deduct the Adhidina; in this case reduce the "*Avamas*" in (ii) by 1.

(iv) Get the remainder from (12 × Kali years + Intercalary months) ÷ 7. Multiply the reainder by 30, and deduct from this the remainder got from (5 × Kali years + "*Avamas*") ÷ 7. Add 1 to this, divide by 7 and find the remainder. This counted from Friday is the Lord of the year, *i.e.* the day of Caitra Śukla-pratipad. (*Note* 2 under 4-6 applies here also).

(v) Multiply the Kali years by $10\frac{149}{576}$. The result are days etc. called "*Ravijāḥ*". Add to this the "*Avamas*" got in (ii). From this deduct the Intercalary months multiplied by 30. The remainder is called "*Deductive*". If the latter is greater deduct the former from it, and call it "*Additive*".

(vi) Avamas are the quotient got by adding the "*Tithis*" in (iii) to the tithis, say T, from Caitra Śukla-pratipad, and dividing by 64. Call this A.

(vii) The remainder from dividing (T — A) by 7, counted from the day of the Lord of the year is the Lord of the Day, *i.e.* the week-day. (*Note* 2 under 4-6 applies here also).

(viii) From (T-A) deduct the "*Deductive*" in (v). If there is only "*Additive*", add this to (T — A). The result is B, the number of civil days from the beginning of the solar year.

(ix) [1] $B^{\circ} - \frac{B^{\circ}}{70} - \frac{2B''}{5}$, is the Mean Sun, Venus or Mercury.[2]

(x) Kali years $\times$ 360° + Mean Sun in degrees etc. is called Grahatanu.

(xi) $\frac{83 \text{ Grahatanu}^{\circ}}{225}$[3] $- \frac{11 \text{ Grahatanu}''}{50} + 13 \text{ Sun} = \text{Mean Moon}.$

(xii) $6 \text{ Rasis} - \left\{ \frac{\text{Grahatanu}^{\circ}}{20} + \frac{\text{Grahatanu}^{\circ}}{270} + \frac{113 \text{ Grahatanu}''}{600} \right\}$
= Rāhu.

---

1. B° means B taken as degrees etc.; B" means B taken as seconds etc. and so on.

2. A distinction is made by me between Mean Sun and Grahatanu in the formulae for the sake of convenience of computation.

3. Grahatanu° means Grahatanu taken as degrees etc.; Grahatanu" means Grahatanu taken as seconds etc. and so on.

(xiii) $3 \text{ Rasis} + \frac{\text{Grahatanu}^{\circ}}{10} + \frac{7 \text{ Grahatanu}'}{9} + \frac{11 \text{ Grahatanu}''}{60} - \frac{\text{Grahatanu}'''}{20}$ = Apogee of the Moon.

(xiv) $2 \text{ Sun} - \left(\frac{37 \text{ Grahatanu}^{\circ}}{900} + \frac{\text{Grahatanu}^{\circ}}{3} + \frac{\text{Grahatanu}''}{100}\right)$

= Venus's Śīghra.

(xv) $4 \text{ Sun} + \frac{3 \text{ Grahatanu}^{0}}{20} + \frac{\text{Grahatanu}'}{8} + \frac{\text{Grahatanu}''}{60}$

= Mercury's Śīghra.

(xvi) $\frac{\text{Grahatanu}^{\circ}}{30} + \frac{8 \text{ Grahatanu}'}{225} + \frac{\text{Grahatanu}''}{300}$ = Mean Saturn.

(xvii) $\frac{\text{Grahatanu}^{0}}{2} + 2 \text{ Grahatanu}' - \frac{\text{Grahatanu}'}{20} + \frac{\text{Grahatanu}''}{50}$

= Mean Mars.

(xviii) $\frac{\text{Grahatanu}^{\circ}}{12} + \frac{22 \text{ Grahatanu}'}{375}$ = Mean Jupiter.

Indeterminate Analysis or Diophantine Equations

In verses 41-52 the solution of Indeterminate equations (Diophantine equations) called *Kuṭṭaka-yukti* is dealt with, with a view to application to problems in astronomy. All problems are reducible to the standard form $\frac{ax \pm b}{c} = y$, where *a* is called the *Bhājya*, *b* is called the *Kṣepa* or *Śeṣa* according as the upper or lower sign is taken, and *c* is called the *Hāra*, all of which are either given or computable from known data. *x* called the *Guṇakāra*, and *y*, called the *Labdha*, are to be found by solving the equation. Bhāskara gives the solution for particular types of problems, which, he says, we may extend to all types.

41. To make the Bhajya and Hara prime to each other, by dividing each by their G.C.M. The method is given for the particular case of the *Hāra* being the civil days in the yuga and the *Bhājya* being the number of cycles of each planet. Find the G.C.M. of the *Hāra* and *Bhājya* by the method of continued division. Divide each

by the G.C.M. They become *Dṛḍha* (irreducible) *Bhājya* and *Hāra*. With reference to these the *Kṣepa* or *Śeṣa* is to be computed.

Note 1. Parameśvara's *Siddāntadīpikā* here explains the method of reduction and its rationale.

Note 2. To illustrate the method let us take the cycles of the Sun in the yuga, 43,20,000 as the *Bhājya* and the civil days in the yuga, 1,57,79,17,500, as the *Hāra*.

1,57,79,17,500	365
43,20,000	3
11,17,500	1
9,67,500	6
1,50,000	2
67,500	4
15,000	2
7,500	

7500 is the G.C.M. Dividing the Bhājya, 43,20,000, by this the *Dṛḍha-bhājya* got is 576. Dividing the *Hāra*, 1,57,79,17,500, the *Dṛḍha-hāra* got is 2,10,389. These also are called *Bhājya* and *Hāra* for short.

42-44. To find the Ahargana and the full cycles gone, given the fraction of the cycle that the planet has gone at the end of the Ahargaṇa. (It is presumed that the *Bhājya* is less than the *Hāra*. The case of the *Bhājya* being greater than the *Hāra* is taken up in verse 47. It is supposed known that the problem is of the *Śeṣa* type and the *Śeṣa* is got by multiplying the fraction of the cycle given, by the *Dṛḍha-hāra*, and taking the value correct to the nearest integer. This will be seen if the equation is framed.)

The following is the method : Begin by dividing the *Hāra* by the *Bhājya* and do the continued division, with the quotients one below the other as they are got. (Even in the process of getting the G.C.M. these quotients would have been got). While proceeding thus, at any stage when an even number of quotients have been got, take the divisor and dividend for the next quotient. Try to guess a number which multiplied by the divisor and with the *Śeṣa* deducted (or with *Kṣepa* added) gives a whole number when divided by the dividend. The guessed number is called *Mati*. The obtained number, we shall call "Obtained". Place the *Mati* below the last (even) quotient got so far. Place the "*Obtained*" below it. Now : (i) Multiply the quotient just above the *Mati* by the *Mati* and add the "*Obtained*". (ii) By this multiply the quotient next above and add the Mati. (iii) By this multiply the quotient still next above and add the result of (i). (iv) By this multiply the quotient still next above and add the result of (ii), and so on. Arrange the results of (i), (ii) etc. one above the

other. Take the topmost and the next numbers thus got. Divide the topmost by the Hāra. The remainder is the Ahargaṇa required. Divide the next by the Bhājya. The remainder is the full cycles gone required. The method is asked to be applied to similar problems *mutatis mutandis*.

Note 1. This may be made clear by an example. At the end of a certain number of days, (*i.e.* Ahargaṇa), the Mean Sun is found to be $3^{r}\ 12^{0}\ 40'\ 1''$. To find the Ahargaṇa and the whole cycles gone.

There are 43,20,000 Sun's cycles in 1,57,79,17,500 days, which reduces to 576 cycles in 2,10,389 days (see verse 41). $3^{r}\ 12^{\circ}\ 40'\ 1''$ expressed as a cycle is 36,901 ÷ 12,96,000. The equation is :

$$\frac{576\,x}{210389} = y + \frac{36901}{1296000},$$ where 'x' is the required

Ahargaṇa and 'y' the number of full cycles gone.

$$\text{i. e.} \quad \frac{576\,x}{210389} - \frac{36901}{1296000} = y$$

$$\text{i. e.} \quad \frac{576\,x - (210389 \times 36901) \div 1296000}{210389} = y$$

$$\text{i. e.} \quad \frac{576\,x - 60000}{210389} = y$$

Thus 60,000 is the *Śeṣa*.

The continued division and work is done thus :

2,10,389	365	(iv)	6,58,86,926
576	3	(iii)	1,80,384
[3,758 / 3,029]			
149	1	(ii)	46,766
129	6	(i)	40,086
20	6680		
9	6		

$$\frac{9\ \text{Mati} - 60,000}{20} = \text{“}\textit{Obtained}\text{”}$$

One Mati is 6680 and the "*Obtained*", 6.

(i)	6 ×	6,680	+	6	=	40,086
(ii)	1 ×	40,086	+	6,680	=	46,766
(iii)	3 ×	46,766	+	40,086	=	1,80,384
(iv)	365 ×	1,80,384	+	46,766	=	6,58,86,926

The top number is 6,58,86,926. The next is 1,80,384. 6,58,86,926 divided out by the Hāra, 2,10,386, leaves the remainder 35,169, which is the Ahargaṇa required, called *Gunakāra*. The next number, 1,80,384, divided out by the Bhājya, 576, leaves the remainder 96, which is the *Labdha*, here the full cycles gone.

Note 2. The Ahargaṇa got is that which pertains to the shorter yuga of 2,10,389 days, it is clear. The wanted Yuga-Ahargaṇa may be in any of the shorter yuga. So the Yuga-Ahargaṇa is n × 2,10,389 + 35,169, where 'n' is any integer. The corresponding cycle is n × 576 + 96. Thus the Ahargaṇa may be 35,169 ; 24,45,558; 4,55,947 and so on, with the corresponding cycles 96, 672, 1248 and so on. This is mentioned by the author in verse 50.

45-46a. Here a device is given to avoid the difficulty when the *Śeṣa* (or *Kṣepa*) is large, as it would generally be. It consists in using 1 as *Śeṣa* (or *Kṣepa*) and doing the operation as instructed. The top and next numbers got should be multiplied by the *Śeṣa* (or *Kṣepa*) and then the *Guṇakāra* and *Labdha* are to be found.

Note 1. Let the last example be taken.

2,10,389	365	(iv)	94,602 × 60,000	= 5,67,61,20,000
576	3	(iii)	259 × 60,000	= 1,55,40,000
149	1	(ii)	67	
127	6	(i)	58	
20	9			
9	4			

$\frac{9\ Mati - 1}{20}$ = "*Obtained*". One Mati guessed is 9, and the "*Obtained*", 4. The top number, 94,602, multiplied by the Śeṣa, 60,000, gives 5,67,61,20,000, which divided out by 2,10,389 gives the

same remainder 35,169, as Guṇakāra. The next number 259 multiplied by 60,000, the Seṣa, gives 1,55,40,000, which divided out by 576 gives the same remainder 96 as Labdha.

Note 2. Another device not mentioned by the author may be added here for convenience. Divide the Seṣa (or Kṣepa) by the Bhājya and find the quotient and remainder. Keep the quotient separate, and use the remainder here as Seṣa (or Kṣepa) in doing the work. To the Ahargaṇa got add or subtract the separately kept quotient according as the type is Seṣa or Kṣepa. This will be the real Ahargaṇa. The cycle is not affected.

Thus, in our example, 60,000 divided by 576 gives the quotient 104 and the reaminder 96. 96 is to be used as Seṣa. 96 × 94,602 = 90,81,792, which divided out by 2,10,389 gives 35,065 as Gunakāra. This plus 104 gives 35,169. 96 × 259 = 24,864, which divided out by 576 gives the same remainder 96 as cycles.

46b. **The manner of getting the Sesha (or Kshepa)** from the given condition is here mentioned. The Śeṣa (or Kṣepa) belongs to the Bhājya class, and so the given Rāśi etc. must be expressed as a fraction of that class in the first instance. This should be multiplied by the Hāra to get the Śeṣa (or Kṣepa). For instance in our example, the Bhājya is cycles. So 3^r 12° 40' 1'' was expressed first as the fraction of a cycle, *viz*. 36,901 ÷ 12,86,000, and then multiplied by the Hāra 2,10,389, and the Śeṣa 60,000 got.

47. The case where the Bhājya is greater than the Hāra is taken up: If the Bhājya is greater than the Hāra, divided the Bhājya by the Hara and place the quotient separate. With the remainder as the Bhājya do the work as mentioned before, and get the Guṇakāra and Labdha. The Guṇakāra is the real Guṇakāra; but to the Labdha add the product of the Guṇakāra and the separately kept quotient. This is the real Labdha.

Note 1. This rule is of the nature of another device to reduce work. An example will make the rule clear:

In computing the Moon for a certain Ahargaṇa, let the result got end in 31' 12''. To find the Ahargaṇa and full degrees gone.

In the yuga of 1,57,79,17,500 days the Moon passes 5,77,53,336 × 360 degrees. Doing the reduction by verse 41, we get 56,80,656 degrees (Bhājya) for 4,31,125 days (Hāra). The Śeṣa, 31' 12", expressed in degrees is 13/25. The Bhājya is greater than the Hāra. Dividing 56,80,656 by 4,31,125 we get the quotient 13 (which we keep separate) and the remainder 76,031 which is to be used as Bhājya. The fraction of a degree, 13/25, multiplied by 4,31,125 gives the Śeṣa 2,24,185. Doing the work as before we get the Guṇakāra 3,96,635, which is the Ahargaṇa. The Labdha got is 69,948. The separately kept quotient 13 multiplied by the Guṇakāra 3,96,635, plus the Labdha 69,948, is the real Labdha, *i.e.* here degrees wanted, 52,26,203. Converted into cycles etc. (if necessary), this is $14{,}517^{c}\ 2^{r}\ 23^{\circ}$.

Note 2. Under this the *Bhāṣya* contains a method to get the Mati. The *Siddhāntadīpikā* after explaining this gives its own method. Several examples are also worked in the *Bhāṣya*.

48. **The type of problem called Vara-Kuttaka.** The Rāśi etc. of a planet on a particular week-day is given. The problem is to find when the planet has the same Rāśi etc. on another given week-day.

In this type the days left over after dividing out the Dṛḍha-hāra of the previous problems by 7 is the Bhājya. 7 is the permanent Hāra. The number of days from the given week-day to the required week-day is the Śeṣa. The Guṇakāra got from this Kuṭṭaka is to be multiplied by the days forming the Dṛḍha-hāra and added to the given day if any.

Example : The Sun was found to be $3^{r}\ 12^{\circ}\ 40'\ 1''$ at the beginning of a Tuesday. When will this again happen at the beginning of a Friday?

In the case of the Sun the Dṛḍha-hāra is 2,10,389 days, which divided out by 7 leaves the remainder 4, which is the Bhājya; 7 is the Hāra. From Tuesday to Friday, there are 3 days, which is the Śeṣa. The work of finding the Guṇakāra and Labdha is simple,

10

because here they are the Mati and "Obtained" respectively. (4 × Mati — 3)/7 = "Obtained", gives 6 for Mati or Guṇakāra, (and 3 for "Obtained" or Labdha). After 6 × 2,10,389 = 12,62,334 days, the Sun will have 3ʳ 12° 40' 1" at the beginning of a Friday.

Note 1. That this will happen subsequently also, at intervals of 7 × 2,10,389 days from this date is obvious.

Note 2. The second problem given under this by the *Bhāṣya* is more complicated than the first. In such cases, where two or more planets occur, the L.C.M. of their individual Dṛḍha-hāra should be taken as the combined Dṛḍha-hāra and work done.

49. It may be that the Rāśi etc. of a planet is given not for the day, but for some division of a day like the end of some unknown number of yāmas or nāḍis. How to find the yāmas or nāḍis is given here.

The method is to take the yuga-yāmas or yuga-nāḍis, and reduce them with reference to the respective yuga cycles of planets and employ these as Hāra. The Guṇakāra obtained will be in yāmas or nāḍis, instead of days.

The following working rule is given: If it is yāma take 8, if nāḍi take 60 and so on, *i.e.* the number of times it is contained in a day. If possible reduce this number and Bhājya with reference to each other, and use this Bhājya only. Multiply the Dṛḍhahāra days by the reduced number got here, and use this as Hāra. Multiply the Śeṣa too by this reduced number and use this as Śeṣa. In the place of the Ahargaṇa the number of yāmas (yāma-gaṇa) or numer of nāḍis (nāḍi-gaṇa) will be got.

Example: The Mean Sun has been computed for the end of a certain number of full nāḍis in a particular day and it is 1ʳ 22° 31'. Find the number of nāḍis (nāḍi-gaṇa) and from that the Ahargaṇa.

There are 60 nāḍis in a day. So take 60. The Dṛḍhabhājya with reference to the Dṛḍhahāra in Ahargaṇa is 576, which is known. Reducing 60 and 576 we get 5 and 48 respectively. So 48 is the Bhājya. Multiplying the known Dṛḍhahāra days 2,10,389 by 5, we have 10,51,945 as Hāra. The fraction of the cycle gone is 3,151÷21,600 which multiplied by 2,10,389 would give the

Śeṣa of the old problem. But now this is to be multiplied by 5 and the Śeṣa is 1,53,457. Doing the work with these, the Nādi-gaṇa obtained is 5,07,254, or Ahargaṇa 8,454 and 14 nāḍis.

Note. Of course this plus any multiple of 10,51,945 nāḍis (*i.e.* 17,532 days, 24 nāḍis) is also the answer.

50. The use of the solution obtained is given here: The solution is only one of a series of values satisfying the equation. So, if *n* times the Hāra is added to the Guṇakāra, that will also satisfy the equation, the Labdha in this case being the Labdha got plus *n* times the Bhājya. (We have mentioned this already under 42-44). What is in the mind of the poser of the problem may be any one of these values. So, we must give the series of solutions one after another and ask him whether he is satisfied with the answer given, and stop when he is satisfied.

51. If instead of the Rāśis etc. gone, the Rāśis etc. to go to finish the cycle is given in the problem, then the problem becomes one of the Kṣepa type. In guessing the Mati this must be remembered and in the device of verse 45, *plus 1* is to be used for Mati instead of *minus 1*. Otherwise the solution is similar. Only the cycles got as Labdha should be reduced by *1*, the reason for which is obvious.

Note. We can also make this a "Rāśis etc. gone" problem by deducting the Rāśis etc. to go from 12 Rāśis and taking the remainder as Rāśis etc. gone.

Example: The Mean Sun was found for a certain Ahargaṇa, and the only thing remembered about it is that the Rāśis etc. required to complete the cycle was 8^r 17^0 19' 59". To find the Ahargaṇa and the full cycles gone.

If after the 4th quotient of the continued division the Mati is guessed with the Kṣepa as 1, the Mati is 11 and "Obtained" 5. Using these we get 35,169 as Ahargaṇa. The cycles got is 97 which reduced by 1, gives 96 cycles gone.

52a. **To find the Ahargana when the sum of the computed Rasis etc. of two planets, or their difference, is given.** In these cases, the sum of the yuga cycles of the two planets, or their difference, is to be taken as the yuga cycles which is the Bhājya. The days in the yuga are the Hāra. They are to be reduced as usual.

The sum or difference of Rāśis given is to be expressed as a fraction of a cycle and the Śeṣa got from it. The rest of the work is the same as that of the ordinary type.

52b. **A method to solve Diophantine equations with two remainders, called Dvicchedagra.** The problem is of the following type. The positions in Rāśis etc. of two planets are known for a certain Ahargaṇa now forgotten. To find this Ahargaṇa.

Bhāskara here only says, 'Kuṭṭaka is also to be done by using the remainder of each, and by using the reduced yuga cycles and yuga days of each'. By 'the remainder of each' we may take him to mean the Ahargaṇa obtained as solution in a Kuṭṭaka of the ordinary type to satisfy a specified position in Rāśis etc. But how these are to be used is not stated by him. It is not that he does not know the method. He has elaborately dealt with such types in his *Āryabhaṭīya Bhāṣya, Gaṇita Pāda*, 32-33. Both the *Bhāṣya* and the *Siddhāntadīpikā* quote the two *āryās* of Āryabhaṭa, give the methods, and explain how different types can be solved.

The method is as follows: First find the Ahargaṇa when planet *A* is in its given position. Then find the Ahargaṇa when planet *B* is in its given position. These two Ahargaṇas are called *Agras*. Note down the Reduced Hāra from which the greater Agra was got and the Reduced Hāra from which the Lesser Agra was got. Divide the two Reduced Hāras by their G.C.M. if any, so that they become prime to each other. Note down the G. C. M. By the same G.C.M. divide the difference between the two Agras. If the difference is not so divisible, the problem is impossible. (*Cf.* also Bhāskarācārya II in his *Līlāvatī: yena cchinnāu bhājyahārau na tena kṣepaś caitad duṣṭam uddiṣṭam eva*). After this the continued division etc. is to be done. First divide out the Reduced Hāra of the greater Agra by the Reduced Hāra of the Lesser Agra. Not counting this quotient, continue the division and do the Kuṭṭaka with the difference between the two Agras as Kṣepa (not Śeṣa) in getting the Mati. Find in the usual way the topmost number. Divide out this number by the Reduced Hāra of the Lesser Agra. The remainder multiplied by the Reduced Hāra of the greater Agra and multiplied by the noted G.C.M., if any, with the greater Agra added, is the Ahargaṇa required.

Example: In computing the Mean Sun and Mean Moon for a certain Ahargana, $10^r\ 12^0\ 47'\ 13''$ is got as the Mean Sun and $2^r\ 12^0$ as the Mean Moon. To find the Ahargaṇa.

We find the Ahargaṇa when the Sun is 10^r 12° 47' 13'' by the method already given. It is 37,939 and this is one Agra. We find the Ahargaṇa when the Moon is 2^r 12^0. It is 8,62,250. This is the other Agra. The Lesser Agra is 37,939 and the Reduced Hāra from which this was got is 210,389. The greater Agra is 862,250 and the Reduced Hāra from which this was got is 21,55,625. These two Hārās have a G. C. M., 3449. This G. C. M. can divide the difference between the Agras, 8,24,311 So reducing all three by the G. C. M. 3449, we have the still more reduced Hāra of the Lesser Agra as 61, of the Greater Agra as 625, and of the difference between the two Agras as 239, this last being the Kṣepa. Now divide out the Hāra of the Greater Agra, 625, by the Hāra of the Lesser Agra, 61, and get the remainder 15, and the continued division begins with dividing 61 by 15.

61	4	(ii)	956
15	15	(i)	239
1	0		
0	239		

$\frac{O \times \text{Mati} + 239}{1}$ = "Obtained", gives 239, when Mati is O. The top number got is 956. This divided by the Hāra of the Lesser Agra, 61, leaves the remainder, 41. This multiplied by the Hāra of the Greater Agra, 625, and by the noted G.C.M., 3449, gives 8,83,80,625. Adding the greater Agra, 862, 250, we get 8,92,42,875 as Ahargaṇa, which would satisfy the condition.

Note. Here the *Bhāṣya* gives different types as examples, like *Dvicchedāgrakakṣyā Kuṭṭaka* and *Tricchedāgra Kuṭṭaka*. Then it gives a new interpretation of the half-verse and gives examples to illustrate it. The *Siddhāntadīpikā* quotes alternative methods to do the Kuṭṭaka.

CHAPTER II

In this chapter the Correction of the Mean planets for Deśāntara, *i.e.* Correction for difference in longitude of the place east or west of the standard meridian is dealt with.

Desantara Correction

1-2. Certain cities are listed through which the standard meridian passes, among which *Laṅkā* and *Ujjain* are important.

3-5. The method of computing the *Deśāntara* advocated by certain people is condemned here, as being only approximate.

6. The method advocated by certain others is here dismissed as practically useless.

7. **Desantara-kala.** The difference between the times of a computed and observed eclipse is mentioned as the correct *Deśāntara-kāla* to compute the correction.

8. Another correct method is here given. The interval between Sun or Moon rise or setting is to be computed from theory. The same interval is to be observed with a water-clock. From the difference between them the Deśāntara-kāla can be found, and thence the Deśāntara.

9. The criteria for the meridian of observation being east or west, of the standard meridian is given. If from verse 8, there is an observed earlier rise of the Moon, or if in verse 7, the observed time of eclipse is later than the computed time, the place is east, otherwise west, of the standard meridian.

10a. **Computation of the Desantara correction.** Multiply the daily Mean motion of the planet by the Deśāntara-kāla got in nāḍis and divide by 60. The result is to be added to the Mean planet if the place is west, subtracted otherwise. (Do the opposite in the case of *Rāhu*).

10b. The circumference of the earth (in yojanas) multiplied by the cosine of the latitude and by the Deśāntara-kāla in nāḍis, and divided by 60, gives the distance of the place east or west of the standard meridian in yojanas.

CHAPTER III

Problems involving time, space and direction and depending generally for their solution on spherical trigonometry are dealt with in this chapter. At the end, the celestial latitude and longitude of the Junction stars of the 27 asterisms are given.

1. **Gnomon and Shadow.** The preliminary operations for getting the shadow, like levelling the floor, fixing the (12-inch) gnomon and the drawing of a circle with the gnomon as centre, are described here.

2. **The method for finding the north-south line** by means of the shadow is given. Mark the two points where the shadow enters or emerges from the circle drawn. With these points as centres draw two circles of equal radius intersecting each other. The common chord is the north-south line. The east-west line is perpendicular to this.

3. For the sake of convenience of observation another method for the same is given. At any three times in the day mark points at the tips of the shadows. Find the centre of the circle passing through the three points. The line joining the centre and the foot of the gnomon is the north-south line.

4. The relation, $\sqrt{144 + \text{shadow}^2}$ = *Chāyākarṇa*, otherwise called the radius (R) of the *Svavṛtta*, is given.

5. **Great Shadow (Maha Chaya) and Great Gnomon (Maha-Sanku).** Shadow × *Trijyā* ÷ R is called the Great Shadow (*Mahā-cchāyā*). 12 × *Trijya* ÷ R is called the Great Gnomon (*Maha-śaṅku*). The Great Shadow at noon on the day when the Sun is on the equator, is called the *Akṣajyā* (*Sin* ϕ, Sine Latitude). The corresponding Great Gnomon is *Lambajyā*, (Cos ϕ, Sine Co-latitude or Cosine Latitude).

6. **Apakramajya, Dyujya, Ksijiya.** 1397 × Sine Longitude of the Sun ÷ Trijya = Sine Declination of the Sun (*called Apakramajyā*, Sin δ). Cos δ = Dyujya, *i.e.* radius of the Diurnal circle. Sin ϕ × Sin δ/Cos ϕ = *Kṣitijyā*.

7. **Carajya.** Kṣitijyā × Trijyā ÷ Dyujyā = Carajyā. Arc Carajyā (*i.e. Cara* or *Carārdha*) is the Declinational Ascensional Difference in prāṇas or sixths of vināḍis.

8. **Carapranakhandas.** —60, —48, —20½, +20½, + 48 +60, +60, + 48, +20½, — 20½, — 48, — 60, multiplied respectively by 12 Sine ϕ ÷ Cos ϕ, give the *Caraprāṇakhaṇḍas* when the Sun is in Aries and the succeeding Signs.

9-10a. **The Right Ascensional Difference (Lankodaya-Pranakhandas).** Multiply Sine 30°, Sine 60°, Sine 90°, each by Cos 24° (*i.e.* 3141) and divide by the cosines of the respective declinations. Find the arcs of the results taken as sines. The first, the second minus the first, and the third minus the second, are the *Laṅkodaya-Prāṇakhaṇḍas*. They are respectively 1670, 1795, 1935 (for the first

three Signs from Aries, and for the succeeding Signs, in order, 1935, 1795, 1670, 1670, 1795, 1935, 1935, 1795, 1670).

10b. **Oblique Ascensional Difference (Lagnamana or Rasimana).** The combination of the result of vere 8 and verses 9-10a gives the *Raśimāna.*

11. **Method to find the Great Gnomon (GG) and the Great Shadow (GS) on any midday.** When the Sun is in the northern hemisphere, take $(\phi - \delta)$; when in the southern hemisphere, take $(\phi + \delta)$. This is the Zenith Distance (ZD). Sine ZD is the GS and Cos ZD is the GG (or Sine Altitude).

12. An alternative method for the midday GG is given. (*Dyujyā* $\pm$ *Kṣitijyā*) Cos $\phi \div$ *Trijyā*, is the GG when the Sun is in the northern and southern hemispheres respectively. GS$= \sqrt{\text{Trijya}^2 - \text{GG}^2}$.

Sun's Declination and Longitude

13-15. With the midday shadow and the Latitude (ϕ) given, a method is given to find the Sun's declination. By verse 5 above, get the GS, *i.e.* Sine ZD. From this get the arc ZD (called *Avanati*). (i) When the shadow is southward, ZD $+ \phi = \delta$, and the Sun is in the northern hemisphere; (ii) When the shadow is northward and ZD is less than ϕ, $\delta = \phi$—ZD, and the Sun is in the northern hemisphere; (iii) when the shadow lies northward and ZD is greater than ϕ, δ = ZD—ϕ, and the Sun is in the southern hemisphere.

16. This gives a method to get the Sun from declination, δ. Find the longitude l from the formula, Sin l=Sin $\delta \times$ Trijyā $\div$ 1397 (see verse 6). If the Sun is in the northern hemisphere, l or $(6^r - l)$ is the longitude of the Sun. If the Sun is in the southern hemisphere, $(6^r + l)$ or $(12^r - l)$ is the longitude of the Sun.

17. *This gives* ϕ when the longitude of the Sun and the midday shadow are known. Find δ from the longitude of the Sun using verse 6. Find ZD using verse 5. (i) If the Sun is in the northern hemisphere and the shadow lies southward, $\phi = (\delta - \text{ZD})$. (ii) If the Sun is in the northern hemisphere and the shadow lies northward, $\phi = (\delta + \text{ZD})$. (iii) If the Sun is in the southern hemisphere, $\phi = (\text{ZD} - \delta)$.

Note. These cases are the converses of those in verses 13-15.

18-20. **To get the Great Gnomon at any time of the day, the time being known, and from this the shadow.** Take the nāḍis elapsed from sunrise, or to elapse for sunset if afternoon. Deduct the *Carārdha* from this if the Sun is in the northern hemisphere, and add if in the southern hemisphere. Convert these nāḍis into degrees at 6° per nāḍi and find its sine; call this "*Sine*". Multiply this by *Dyujyā* and divide by *Trijyā*. Deduct the *Kṣitijyā* from the result if the Sun is in the southern hemisphere, add if in the northern hemisphere. Multiply this by Cos ϕ and divide by *Trijyā*. This is the Great Gnomon at the time. From this the GS is got by verse 12.

21-22. **Another method for GG.** Multiply Sin (Lagna — Sun) by Cos ZD of the Nonagesimal *(Tribhona-Lagna)*, and divide by *Trijyā*. The result is GG. (Lagna is the Orient Ecliptic point. GS is got as mentioned in 18-20).

Note. But Bhāskara has not shown how Cos ZD of the Nonagesimal is to be derived. He expects us to use the rough *Dṛkkṣepajyā* given later in chapter V, verse 19.

23. **A third method for GG.** Do the work of 18-20 up to finding the "*Sine*". Then GG = ("*Sine*" $\pm$ Carajyā) $\times$ Dyujyā $\times$ Cos ϕ $\div$ Trijyā^2, where the upper sign is to be taken when the Sun is in the northern hemisphere and the lower when in the southern hemisphere.

24. **A fourth method for GG.** In the work of verse 23, instead of Cos ϕ use 12 divided by the *Chāyākarṇa* (given by verse 4) of the Sun on the equator. Instead of Trijyā^2 use Trijyā. The GG is got.

25. A possible difficulty in applying 18-20, 23 and 24 is tackled. It may be that the nāḍi is so small that the *Carārdha* is not subtractable. In that case, in 18-20, deduct the nāḍis from the *Carārdha* and proceed. After division by Trijyā, deduct the result from *Kṣitijyā*. In 23 and 24 deduct "*Sine*" from *Carajyā* and continue the calculation.

26. **A method to get the Sun's GG in the night. For this, rules in verses 18-25 are to be used with the modification that wherever the Carārdha or Carajyā is additive, it has to be taken as subtractive, and vice versa.**

27-29. **To know the time of the day from the Shadow.** Three methods are given, which are only the inverse operations of getting the shadow from the given time. Verse 27 gives the inverse of verses 18-20 ; Verse 28 is the inverse of 23 ; verse 29 is the inverse of verse 24. From the shadow, first the GG is got by verses 4-5. Then by inverse operation, severally, the time is got.

30-32. **The Orient Ecliptic point or Udaya-lagna for any given time at any place,** by using the rāśimāna for the place obtained in verse 10b, is here explained. Find the Sun at the time for which *lagna* is wanted. Multiply the rāśimāna of the Rāśi where the Sun is, by the degrees etc. which the Sun is yet to pass in that Rāśi and divide by 30. Deduct the time obtained from the given time and take the Rāśi as gone. Beginning from the next Rāśi deduct one by one the rāśimāna-s of the subsequent Rāśis, taking the Rāśi as gone, one by one. If at last there is no time left for a full rāśimāna to go, multiply the remaining time by 30 and divide by the rāśimāna to go. Degrees etc. are obtained in the rāśimāna to go. That is the *Udaya-lagna* or *Lagna.*

33. **To get the Setting point of the Ecliptic (Asta-lagna)** add 6 rāśis to the Rising point of the Ecliptic (*Udaya-lagna*).

34-36. **Time of the day when the Udaya-lagna at a place is known.** This is the inverse operation of 30-32. Take the Sun at sunrise. Multiply the rāśimāna of the Sun's Rāśi by the degrees etc. which the Sun is yet to pass in that Rāśi, and divide by 30. To the time got, add the subsequent rāśimānas one by one until we come to the Rising Sign (*Udaya-rāśi*). Multiply the degrees gone in the *Udaya-rāśi* by its rāśimāna and divide by 30. Add the time obtained to the time already obtained. The approximate time is got. Using the Sun of this time repeat the operation. The required time of the day is got.

37a. **The Amplitude of the Sun (Arkagra) at rising or setting.** (*Agrā* is Sine amplitude). $Arkāgrā = \dfrac{Trijyā \times Sine\ \delta}{\text{Cos}\ \phi}$. This is north when the Sun is in the northern hemisphere, and south otherwise.

37b-38. **The Sama-sanku, i.e., Great Gnomon when the Sun is on the Prime Vertical (Sama-mandala).** (The condition for the Sun to be at all on the Prime Vertical is that it should be in the northern

hemisphere and at the same time δ is less than ϕ). Multiply the *Arkāgrā* (got by 37a) by Cos ϕ and divide by Sine ϕ. This is the *Sama-śaṅku*. The Great Shadow corresponding to this can be got in the usual manner.

$$i.e.\ \text{Samaśaṅku} = \frac{Arkāgrā \times Cos\ \phi}{\text{Sin}\ \phi} = \frac{Trijyā \times Sin\ \delta \times Cos\ \phi}{\text{Cos}\ \phi \times \text{Sin}\ \phi}$$

$$= \frac{Trijyā \times Sin\ \delta}{\text{Sin}\ \phi}$$

39. **The Natanadi (i.e. the time for or from midday) when the Sun is on the Prime Vertical.** To get this find the *Natabhāga* (*i.e.* Hour-angle, h) from the formula:

$$\text{Cos Natabhāga} = \frac{Sin\ \delta.\ Cos\ \phi.\ Trijyā}{\text{Cos}\ \delta.\ \text{Sin}\ \phi}$$

Divide the Natabhāga by 6. The result is the *Natanāḍī*.

40. Given δ and the Shadow when the Sun is on the Prime Vertical, to find the Natanāḍī. From the Shadow get the GS or Sin ZD by verses 4 – 5. From the formula: Sin Natabhāga = *Trijyā* × *Sin ZD* ÷ Cos δ, find Natabhāga, which divided by 6 gives Natanāḍī.

41. **To find the Sun from the Shadow when on the Prime Vertical.** From the Shadow get the Great Gnomon (*i.e.* Cos ZD) by verses 4–5. Now $\frac{Cos\ ZD \times Sin\ \phi}{\text{Trijyā}} = \text{Sin}\ \delta$.
From this by verse 16 get the Sun.

Note. The Sun can only be in the northern hemisphere.

42-45, 52. **To trace the path of the tip of the gnomonic shadow for any day, given the Sun and ϕ.** From the Sun find Sin δ, by verse 16. Using δ and ϕ compute the Arkāgrā by verse 37a, the Great Shadow by verses 18-25, the Śaṅkvagra by verse 54, and the Shadow by verses 4-5. Add the two Agrās if they are of the same direction and note the direction. If of different directions find their difference and take the direction of the greater. Multiply this by the Shadow and divide by the Great Shadow. Let this be *A*.

Prepare a level ground with the East-West and North-South lines marked on it, crossing at the gnomon. Mark a point distant *A* from the East-West line, north or south of it, in the direction opposite to that of *A*. Draw a line parallel to the East-West line through this point. With the centre at the gnomon and radius equal to the shadow, draw the arc of the circle cutting the parallel at two points. Take these two points. Calculate the Midday shadow (by 13-15) and laying it in the appropriate direction on the North-South line, mark a point at its tip. Draw the circle passing through the three points taken. The tip of the shadow moves along this.

46-51, 52. **To get the directions** by a single observation of the gnomonic shadow, given the Sun and ϕ, and thereby to trace the movement of the shadow tip.

From the observed shadow find the Great Shadow and the Great Gnomon (by 4-5), the Agrā and the Saṅkvagra, and get *A* as in (42-45). This is the base of a right triangle of which the shadow is the hypotenuse. Hence $\sqrt{\text{Shadow}^2 - \text{Base}^2} = \text{Perpendicular}$, *i.e.*, the other side. Construct a rectangle with sides equal to the base and the perpendicular got. Or construct a right triangle with the base, perpendicular and hypotenuse as sides. Make a hole outside one corner, (if in the triangle, outside one end of the hypotenuse), to make the rectangle or triangle rotate round the gnomon. Rotate the instrument so that the diagonal or hypotenuse coincides with the shadow. The base stands North-South and the perpendicular stands East-West. Now mark the East-West and North-South lines through the base of the gnomon. Extend the perpendicular to the other side of the North-South line and mark the point corresponding to the shadow-tip. Compute the Midday Shadow by verses 13-15 and lay it in the appropriate direction on the North-South line and mark a point at the tip. The rest of the work is as in verses 42-45, 52.

53. **Arkagra and Sin ϕ.** (i) Arkāgrā $= \sqrt{\text{Sin}^2 \delta + \text{Kṣitijyā}^2}$. (ii) Sin ϕ = Trijyā × Kṣitijyā ÷ Arkāgrā.

54. **The formula for Sankvagra used earlier is here given.** *Śaṅkvagra = Sin ϕ × Great Gnomon* ÷ Cos ϕ.

The Śaṅkvagra is always South. From this formula, given Śaṅkvagra and the shadow observed, we can get ϕ.

55. The Midday Shadow of the Sun on the Equator is given by 12 × Śaṅkvagra ÷ Great Gnomon.

56-60a. To get the Arkagra and Sankvagra by observation, and thereby the Equinoctial Shadow etc.

Erect a circular platform, level with the eye, with the directions marked, and degrees marked along the rim. With the eye on the western side, view the rising Sun across the centre of the platform and mark the point on the rim through which the Sun is sighted. The angle between this and the East-point is the Amplitude. Its sine is the Arkāgrā.

Observe the shadow at any time wanted. When the Sun is in the southern hemisphere the Natijyā, i.e. the perpendicular dropped from the tip of the shadow to the East-West line minus Arkāgrā, is the Śaṅkvagra. When this is in the northern hemisphere and the Shadow northward, Natijyā + Arkāgrā = Śaṅkvagra. When the Shadow is southward, Arkāgrā — Natijyā = Śaṅkvagra. From this we can get the Midday Shadow of the Sun on the Equator, and from that Sin ϕ and Cos ϕ.

Note. The *Bhāṣya* and the *Siddhāntadīpikā* unnecessarily confine Natijyā to sine Midday Zenith Distance and thus restrict the scope of the work.

60b-61. To find the longitude of a planet when the longitude of another planet is known, as also the interval in time between their rise or culmination or setting.

The interval in nāḍikās multiplied by 6 are degrees. Deduct these degrees from the longitude of the known planet if east, and add if west. The unknown planet's longitude is got.

Note. This rule is rough. A better rule would be to use the Laṅkodayprāṇa (Right Ascensional Difference) if the interval pertains to the culmination, and the Svadeśa-rāśimāna (Oblique Ascensional Difference) if the interval pertains to rising or setting, always using the difference of the region where the planets are situated. For a still better result, the latitude and motion of the planets should be taken into account.

62-70a. The co-ordinates of the Junction Stars, (Yoga-tara) of the twenty-seven principal asterisms are given. 62-66a give the longitudes and 66b- 70a give the latitudes.

Asterism	Longitude	Latitude
Aśvinī	8°	10° N
Bharaṇī	27°	12° N
Kṛttikā	36°	5° N
Rohiṇī	49°	5° S
Mṛgaśīrṣa	62°	10° S
Ārdrā	70°	11° S
Punarvasū	92°	6° N
Puṣya	105°	0°
Āśleṣa	114°	7° S
Maghā	128½°	0°
Purva-Phalgunī	141°	12° N
Uttara-Phalgunī	154°	13° N
Hasta	173°	7° S
Citrā	185°	2° S
Svātī	197°	37° N
Viśākhā	212°	1½° S
Anūrādhā	222°	3° S
Jyeṣṭhā	228°	4° S
Mūlā	241°	8½° S
Pūrva-Āṣāḍha	254°	7° S
Uttara-Āṣāḍha	267°	7⅓° S
Śravaṇa	285°	30° N
Śraviṣṭhā	296°	36° N
Śatabhiṣak	307°	18′ S
Pūrva-Bhādrapada	328°	24° N
Uttara-Bhādrapada	345°	26° N
Revatī	0°	0°

70b-71a. A planet on the same Secondary of the Ecliptic as any Junction Star has the same longitude as the Star, from which the planet's longitude can be known. The distance between the planet and the Junction Star on the Secondary should be got from their latitudes.

71b-74. The latitudinal positions of certain Asterisms and Junction Stars which Bhāskara has determined by observation of their conjunction with the Moon are given here for comparison. These

are those that can come into conjunction with the Moon, of which only Puṣya has been left out. Obviously he expects these values to be used in the determination of occultations of these Stars by the planets. The different asterisms and their latitudes are:

Rohiṇī	4° 16'	Śatabhiṣak	24'
Citrā	1° 35'	Viśākhā	1° 28'
Jyeṣṭhā	3° 20'	Revatī	0
Anūrādhā	2° 30'	Centre of the Maghā group	4°30'

The moon crosses the Vehicle of Rohiṇī when greater than 1°, and the body of Kṛttikā when greater than 2° 40'.

CHAPTER IV

Methods for computing the *True Longitudes* of planets at sunrise at any desired place are given in this chapter, as also the means of finding their daily motions. Methods for computing the *Tithi*, *Nakṣatra* and *Karaṇa*, together with the *yogas Vyatīpāta*, *Vaidhṛta* and *Sārpamastaka* are given.

1-6, 8a. One manner of getting the True Sun is here dealt with, and this is asked to be followed in the case of the Moon and other planets so far as it goes.

First do the correction for Terrestrial longitude (*Deśāntara*) (mentioned in II. 9) in the Mean planet. Deduct the longitude of the Higher Apsis (given in VII. 4, 11-12) from this. The remainder is called Anomaly (*Kendra*). Three Rāśis of Anomaly is a quadrant of the Anomaly. The segments of sines (*i.e.* the *jyākhaṇḍas* 225, 224, 222 etc. given in *Āryabhaṭīya, Gīti*. 12) are for intervals of 3¾ degrees. The remaining rāśis etc. are to be divided by 3¾ degrees, which will give whole segments to be added up. The fractional part of the next segment due to the remainder is to be got by proportion and added. In the odd quadrants the rāśis of Anomaly gone is called *Bhujā* and the part yet to go is called *Koṭi*. In the even quadrants, the rāśis of Anomaly gone is called *Koṭi* and the rāśis to go is called *Bhujā*. Find Sin Bhujā of the Anomaly as mentioned; multiply this by the degrees of epicycle (given in VII. 13,15) and divide by 80. The result is *Bhujā-phala*. If the apsis and the epicyle used pertain to the Equation of the Centre, the *Bhujā-phala* is the Equation of the Centre. This is to be subtracted from the Mean

longitude if the Anomaly lies in the first and second quadrants and it should be added when the Anomaly lies in the third and fourth quadrants. In the case of the Sun and the Moon this gives their True Longitudes. This is known as the **Epicyclic Method.**

2a, 5a. **An alternative method of finding the Bhuja-phala** and applying it is given here.

Note. The Bhāṣya here contains discussions on: (i) whether the Sun's parallax is to be taken into account or not in computing sunrise; and (ii) the planetary orbits and the theory of their motions.

7. **The correction called Bhujantara**, for the difference in sunrise due to the part of the Equation of Time, corresponding to the Equation of the Centre is given here. The Mean daily motion multiplied by the Sun's Equation of the Centre in minutes of arc and divided by 21,600 is to be subtracted or added in the planet according as the Equation of the Centre is subtractive or additive in the Sun.

Note. The True daily motion would do better, but it has not yet been got. So this work is repeated in verse 24.

8b-12. **The method of finding the "True Hypotenuse" or Radius Vector, (called Avisista-karna)**, by successive approximation is given here. As mentioned in verses 1-6 above, find the Bhujā and the Koṭi of the Anomaly pertaining to the Equation of the Centre and find the Bhujā-phala and Koṭi-phala respectively. Add the Koṭi-phala to Trijyā in the case of the fourth and first quadrants and subtract in the case of the second and third quadrants. Square this and add the square of the Bhujā-phala, and find the square-root of the sum. This is the first approximate hypotenuse. Multiply the Bhujā-phala and Koṭi-phala by the hypotenuse and divide by Trijyā. Using these find the hypotenuse again and again, until there is little difference between two successive hypotenuses. This is the "*True Hypotenuse.*"

13. The Trijyā multiplied by the Mean daily motions of the Sun and the Moon and divided by their respective True Hypotenuses gives their True daily motions.

14-17. **An alternative method for the daily motion of the Sun and the Moon.** In the case of the Sun take the last segment used in

finding the Sine of the Bhujā of the Anomaly. Multiply this by the Mean daily motion and by the epicycle pertaining to the Equation of the Centre, and divide by 18,000. Deduct the result from the Mean daily motion in the fourth and the first quadrants and add in the second and third quadrants. The result is the True daily motion of the Sun.

In the case of the Moon find the segments and parts of the segments of Sine Bhujā corresponding to the last part of the Anomaly equal to the Mean daily motion of the Moon. Multiply this by the epicycle and divide by 80. Add it to or subtract it from the Mean daily motion of the Moon as in the case of the Sun. The result will be the True daily motion of the Moon.

18. **Another method for the True daily motion** is suggested. Today's True Sun or Moon *minus* yesterday's, is yesterday's True motion. Tomorrow's True Sun or Moon *minus* today's is today's True daily motion.

19-23. **An alternative method for the True Sun and Moon, known** as the Ex-centric method is given here.

$$\frac{\text{Trijyā} \times \text{Manda-paridhi}}{80} = \text{Antya-phala (Maximum Equation}$$

of the Centre). Find Sin Bhujā of Anomaly (*i.e.* Sin Anomaly) and Sin Koṭi of Anomaly (*i.e.* Cos Anomaly). Now,

$$\text{Hypotenuse} = \sqrt{[(\text{Cos Anomaly} \pm \text{Antyaphala})^2 + \text{Sin}^2\, \text{Anomaly}]}$$

where the upper sign refers to the fourth and first quadrants and the lower to the second and third. Multiply the Antyaphala by the Hypotenuse and divide by Trijyā. Using this as Antyaphala repeat the work and make the Hypotenuse true. Multiply Sin anomaly by Trijyā, divide by the True Hypotenuse and find its arc. Let the Mandocca or longitude of the Higher Apsis be LH. Then :

True Sun or Moon in the First quadrant	= LH + arc
Do. in the second quadrant	= LH + 6 rāśis — arc
Do. in the third quadrant	= LH + 6 rāśis + arc
Do. in the fourth qnadrant	= LH+12 rāśis — arc

Note. Under verse 22 the *Bhāṣya* and the *Siddhāntadīpikā* contain elaborate treatment of how to get very accurate Sine segments and Sines or Cosines.

24. **The Bhujantara correction** (cf. verse 7) **according to the Ex-centric method.** Find the difference between the Sun's Mean and True longitudes in minutes. Multiply this by the (True) daily motion of the planet and divide by 21,600. The resulting minutes are to be added to the True planet if the True Sun is greater than the Mean Sun, and vice versa.

25-27. **The correction for difference in sunrise due to Carardha.** Multiply Sin True Sun by 13 and divide 32. The Sun's declination is got. With this get the Carārdha as in III. 6-7. Multiply the Carārdha in prāṇas by the (True) daily motion of the planet and divide by 21,600. Deduct or add the result in the planet according as the planet at sun-rise or sun-set is wanted, if the Sun is in the northern hemisphere. If the Sun is in the Southern Hemisphere, interchange the addition and subtraction.

28. **Day-time.** When the Sun is in the northern hemisphere, 15 nāḍikās *plus* Carārdha is the half duration of day-time ; when in the southern hemisphere, it is 15 nāḍis *minus* Carārdha. To get night-time, interchange "northern hemisphere" and "southern hemisphere".

29-30. **The Bhujantara of the Moon and other planets** are to be done by using the Equation of the Centre of the Sun ; and the additiveness or subtractiveness of the correction is as in the Sun (see 24). The computation of True Moon is like that of the True Sun.

31-32. **The Tithi** is got thus : Deduct the True Sun from the True Moon and convert into minutes. Divide by 720. The quotient are the Tithis gone. Multiply the remainder by 60 and divide by the difference of their True daily motions. The result are the nāḍis gone in the current Tithi at sunrise. Deduct the nāḍis from 60. The remaining nāḍis give the ending moment of the Tithi gone.

33. **The Karanas** are got thus : Multiply the tithis in the bright fortnight by 2 and deduct 1. Or multiply the tithis in the dark fortnight by 2 and add 1. Divide by 7 in both cases. The Karaṇas *Bava, Bālava, Kaulava, Taitila, Gara, Vaṇija* and *Bhadra* are got. (The Karaṇa's for each half tithi from the second half of Kṛṣṇa-Caturdaśī to the first half of Śukla-Pratipad are, however, *Śakuni, Catuṣpad, Nāga* and *Kimstughna*, respectively).

34. **The Nakshatra of the planet** is got thus : Convert the True planet into minutes and divide by 800. The quotient are full Nakṣatras gone. Divide the remainder by the daily motion. The days etc. gone in the current Nakṣatra would be got.

35. **Yoga**. When the True Sun and Moon together make 6 rāśis, it is the *yoga* called *Vyatīpāta*. When they make 12 rāśis, it is *Vaidhṛta*. And when they make 7^r 16° 40', it is *Sārpamastaka*.

Star-planets

36. What has been said about the Sun should be followed in the case of the Star-planets also so far as they go. What are peculiar are mentioned hereunder.

37-38a. In the case of the Star-planets the Epicycle has to be made True : The difference of epicycles between odd and even quadrants is to be multiplied by the *Utkramajyā* and *Kramajyā* (*i.e.* segments taken in the reverse order and given order) respectively in the odd and even quadrants in the case of the Anomaly pertaining to the Equation of the Centre; and by the *Kramajyā* and *Utkramajyā* (in the odd and even quadrants) in the case of the Anomaly of Conjunction. This is to be divided by Trijyā and added to the lesser epicycle or subtracted from the greater epicycle, according as *Kramajyā* or *Utkramajyā* is used. This makes the epicyle True. (Here the Utkramajyā is of the Koṭi and the Kramjya is of the Bhujā).

38b. The Sine or Cosine of Anomaly is to be multiplied by this corrected epicycle and divided by 80 to get the *Bhujāphala* or *Koṭiphala*.

39–42. The Geocentric True **longitude** of Mars, Jupiter and Saturn is given here, according to the Epicyclic method:

(i) Half the Equation of the Centre got by verses 1-6, 37-38 is to be subtracted or added to the Mean planet according as the Anomaly is within 6 rāśis or more than 6 rāśis.

(ii) This Corrected Mean is to be subtracted from the Śīghrocca or Apsis of Conjunction: the result is the Anomaly of Conjunction. From this the *Śīghra-bhujāphala* is to be obtained by 37-38, and also the *Śīghrakarṇa* (Geocentric radius vector) like getting the first approximate hypotenuse in 8b-12. The *Śīghra-bhujāphala* is to be multiplied by Trijyā and divided by the Śīghrakarṇa and this is to be

converted into arc. This is called the Equation of Conjunction. Half this arc is to be added or subtracted from the Corrected Mean according as the *Śīghra-kendra* (Anomaly of Conjunction) is within 6 rāśis or more.

(iii) Using this Double-corrected Mean, again the Equation of the Centre is to be got and the whole of this is to be applied to the uncorrected Mean. The *Sphuṭa-madhya* (Corrected Mean) is got.

(iv) Using the *Sphuṭa-madhya,* the Equation of Conjunction is again to be calculated and the whole applied to the Sphuṭa-madhya. The result is the Geocentric True planet.

43. The treatment of Mercury and Venus is slightly different. In these cases (i) of 39–42 is not done. The rest is the same. The avoidance of (i) makes it possible to apply (ii) negatively to the Mandocca in operation (iii), and complete the work.

Note. This avoidance of operation (i) for Mercury and Venus is characteristic of the School of Āryabhaṭa.

Excentric method for the Star-planets

In 44-63 the application of the Excentric method to find the Geocentric True longitudes, daily motions etc. of the Star-planets etc. are dealt with.

44-46, 54. The Equation of the Centre should be got by applying the Excentric method (verses 19-23), and applied to the Apsis as in the case of the Sun. The Equation of Conjunction should be obtained as mentioned below and deducted from the Apsis of conjunction, the respective deductives in the four quadrants being: the Eq. of Conj., (6 rāśis—Eq. of Conj.), (6 rāśis + Eq. of Conj.) and 12 rāśis—Eq. of Conjunction). In getting the *Śīghra-karṇa* (Geocentric radius vector) the sum of the Maximum Equation and the Cosine of Anamoly in the case of the first and fourth quadrants, and their difference in the second and third quadrants are to be used. The *Manda-karṇa* (Radius vector) *alone* is to be done by successive approximation.

47-51a. The following procedure is to be followed in the case of Mars, Jupiter and Saturn :

(i) First do the *Manda-sphuṭa* as in the case of the Sun. Find the difference between this and the Mean, divide by 2, and add it

to the Mean if the Manda-sphuṭa is greater, and subtract if less. Let the result got be called *Sakṛt-siddha*.

(ii) Deduct the *Sakṛt-siddha* from the Apsis of Conjunction. Using the Anomaly got, do the *Śīghra-sphuṭa*. Find the difference between this and the *Sakṛt-siddha*, divide by 2 and add it to the *Sakṛt-siddha* if the *Śīghra-sphuṭa* is greater; subtract if less. The result is called *Dvi-siddha*.

(iii) Again do the *Manda-sphuṭa* with the *Dvi-siddha* as mean. We get the *Dvisiddha-Mandasiddha*. Find the difference between this and the *Dvi-siddha*, and add it to the original Mean planet if the *Dvisidda-Mandasiddha* is greater, and subtract if less. The result is *Sphuṭa-Madhya*.

(iv) Deduct the *Sphuṭa-Madhya* from the Apsis of Conjunction. Using this as Anomaly do the *Sīghra-sphuṭa*. This is the **True planet.**

51b-53. **The procedure in the case of Mercury and Venus.**

(i) First do the *Śīghra-sphuṭa* using the Anomaly of Conjunction (got by deducting the Mean planet from the Apsis of Conjunction). Find the difference between the Śīghra-sphuṭa and the Mean, divide by 2 and subtract from the Apsis of the Equation of the Centre if the Sīghra-sphuṭa is greater than the Mean, and add if less. This is the Corrected Apsis of the Eq. of the Centre. (ii) Using this do the Manda-Sphuṭa. Sphuṭa-madhya is got. (iii) Deduct the Sphuṭa-madhya from the Apsis of Conjunction. Using this as Anomaly do the Śīghra-sphuṭa. The result is the **True planet.**

Note. The Sid-Dīpikā here contains two long quotations. The first consisting of 13 stanzas justifies the excentric and epicyclic methods used by Bhāskara. The second quotation of 32 stanzas gives instructions for the graphical representations of the two methods, as criteria for the correctness of the same.

55-56b. **A rough rule for the beginning, maximum and ending of Retrograde motion.** Take half the difference between the True planet and the Mean. Add this to the Apsis of Conj. if the Mean is greater than the True, and subtract if less. Subtract the True planet from this Corrected Apsis. If the remainder is 4 rāśis Retro-

grade motion is about to begin (*i.e.* if greater than 4 rāśis, there is Retrograde motion, if less, no Retrograde motion). If the remainder is 6 rāśis the Retrograde motion is maximum. If it is 8 rāśis the Retrograde motion will soon be ending.

56b. **The True Daily Motion** is the difference between the True planets of two consecutive days.

57-62. **The True Daily Motion** is calculated here by a different method. The method presupposes the excentric method as having been already applied in finding the True planet for the previous day, and uses the intervals of Sines, Karṇa etc. got there.

For Mars, Jupiter and Saturn : (i) Multiply the Mean daily motion by the current Sine interval of the *Sakṛit-siddha* work and the True epicycle of the Equation of the centre and divide by 18,000. According to the quadrant of the Anomaly subtract, add, add and subtract, half this in the Mean daily motion. Let this he called *Sakṛt-saṃskṛta.* (ii) Deduct this from the daily motion of the Apsis of Conjunction. Multiply this by the current Sine interval of the *Dvi-siddha* work and by the True epicycle of Conjuction, and divide by 18,000. Multiply the result by *Trijyā* and divide by the related *Karṇa.* Take half this and, according to the quadrant of the Anomaly of Conjuction, add, subtract, subtract, and add in the *Sakṛt-saṃskṛta.* (iii) Using this as the Mean daily motion, repeat (i) using the current Sine etc. of Sphuṭa-madhya operation, but apply the whole instead of half the result to the Mean daily motion. This is *Manda-sphuṭa-bhukti.* (iv) Using this as *Sakṛt-saṃskṛta* repeat (ii) using the current Sine of the final operation, applying the whole result instead of half, to the *Manda-sphuṭa-bhukti*. The result is the **True daily motion.** If in the second and third quadrants the result is greater than the *Manda-sphuṭa-bhukti* and cannot be subtracted from it, deduct the *Manda-sphuṭa-bhukti* from it and the result is **Retrograde motion.**

For Mercury and Venus: (i) Deduct the Mean daily motion from the daily motion of the Apsis of Conjunction. Multiply this by the current Sine interval of operation (i) of (51b-53), by the Corrected epicycle and by Trijyā, and divide by 18,000 and the Karṇa there. Take half this and add, subtract, subtract, add, to the Mean daily motion, according to the quadrant of the Anomaly of Conjunction. (ii) Multiply the current Sine interval of operation (ii) of (51b-53) by this Corrected Mean daily motion, and by the True epicycle, and

divide by 18,000. Subtract, add, add, subtract the result in the original Mean daily motion. This is *Manda-sphuṭa-bhukti*. (iii) Subtract this from the daily motion of the Apsis of Conjunction. Multiply this by the current Sine segment of operation (iii) of (51b-53) and by the True epicycle there, and divide by the Karṇa. Add, subtract, subtract, add the result to the *Manda-sphuṭa-bhukti*. **The True daily motion** is got. If the subtraction cannot be made, deduct the *Manda-sphuṭa-bhukti* from the result, and the remainder is Retrograde daily motion.

Note: Under 57-60 there is a long discussion in the *Bhāṣya* about the explanation of the process and the propriety of the addition, subtraction etc. mentioned therein.

63. **Sama-kala.** Multiply the remainder in minutes after getting the full Tithis (see 31-32) by the True daily motion of the Sun on the one hand and of the Moon on the other, and divide by the difference of their True daily motions. Deduct what is got, from the Sun and from the Moon respectively. The Sun and the Moon will have the same minutes. (If the Tithis gone is Pūrṇimā, the Sun and the Moon will differ by exactly 6 rāśis; if *Amā* they will be exactly equal).

If in the work above, 720 *minus* the remaining minutes is used, and instead of deducting, the results are added to the Sun and the Moon, then also there will be equality of minutes etc. (Here if the Tithi to come is *Pūrṇimā*, there will be a difference of exactly 6 rāśis, and if *Amā*, they will be exactly equal).

Note. This work is necessary in the next chapter to find the Sun and the Moon at the end of the *Parva*, for the computation of eclipses.

CHAPTER V

Eclipses, Solar and lunar, are dealt with in this chapter. Verses 1-67 deal with the Solar eclipse mainly, with instruction to use it for the Lunar eclipse *mutatis mutandis*. The rest of the chapter is devoted to the Lunar eclipse.

1-7. **Certain elements required are given here: The Radius of the Sun's orbit** is 459,585 yojanas, and of the **Moon's** 34,377. **The Radius Vector** (*yojana-karṇa*) is got by multiplying this by the respective True hypotenuse in minutes (got in IV. 8-12) and dividing by Trijyā.

The diameter of the Sun, Moon and the Earth in yojanas are 4410, 315 and 1050. The diameters of the Sun and the Moon, multiplied by Trijya and divided by their respective Radius Vector give the respective **Angular diameter** (*Liptā-vyāsa*).

An Alternative method for the Angular diameters, and one for the Earth's Shadow are as follows: 5/9 of the True daily motion of the Sun in minutes, *plus* $\frac{1}{4}$ of the result taken as seconds, is the angular diameter of the Sun. The True daily motion of the Moon in minutes divided by 25, *minus* $\frac{1}{4}$ of the result taken as seconds is the angular diameter of the Moon. The True daily motion of the Moon in minutes divided by 10, *plus* 1/16 of the daily motion in minutes taken as seconds, is the angular diameter of the Shadow.

Note. Under 2-4 the *Bhāṣya* discusses the size, shape etc. of the Sun, Earth and Moon, the Earth's rotation etc. Under 7 there is a discussion about what is Rāhu.

8-11. **The Computation of** the **Madhya-lagna (Meridian Ecliptic point)** required for *Dṛkkṣepa* (Zenith Distance of the Nonagesimal) is here give. Find the interval between the desired time and midday. If forenoon find the Right Ascenional difference proportionate to the degrees of the Sun *gone* in its Rāśi, and deduct it from the interval. Omit the fraction of the Rāśi from the Sun. Deduct also as many Right Ascensional differences of previous Rāśis as can be done, and deduct the Rāśis from the Sun. For the time left, find by proportion the degrees of the next previous Rāśi and deduct this also from the Sun. The result is *Madhya-lagna* (Meridian Eclipiic point). If afternoon, find the Right Ascensional difference proportionate to the degrees of the Sun, *to go* in its Rāśi, and deduct from the interval. Take the Sun's Rāśi as full. Add the subsequent Rāśis one by one, deducting their Ascensional differences one by one from the remaining interval. Find the degrees in the next Rāśi proportionate to the remaining interval and add this also. This is the *Madhya-lagna*.

12. This says that the **Udayajya (Amplitude of the Rising point)** of the ecliptic and of the Moon's orbit are distinct, as also their **Madhyajya (Sine Zenith distance of the Meridian point** of the ecliptic and of the Moon's orbit); and therefore they must be found separately.

13-16a. **The Udayajya of the Sun and of the Moon.** (i) Multiply Sine Udayalagna by 1397. This is Sine declination of the Udayalagna. Divide this by Cos ϕ. The result is the *Udayajyā* with

reference to the Sun. (ii) Deduct the Moon's Ascending Node from the Udayalagna and find its sine. Multiply this by 15 and divide by 191. This is the latitude of the Rising point of the Moon's orbit. This is North if the Asc. Node is less than the Udayalagna is less than the Des. Node; otherwise South. Add this to the declination got in (i) if both are of the same direction. and deduct one from the other if of different directions. Multiply the sine of this by Trijyā and divide by Cos ϕ. This is the *Moon's Udayajyā*.

16b-18. **The Madhyajya of the Sun and the Moon.** (i) The *Madhyajyā* with reference to the Sun: Find the declination of the Meridian Ecliptic point. Add this to the latitude of the place ϕ (which is always south) if of the same direction and note the direction. Deduct one from the other if of different directions, and note the direction of the greater. The sine of this is the *Madhyajyā* with reference to the Sun. (ii) The Moon's *Madhyajyā* is obtained by taking into consideration the latitude of the Meridian point of the Moon's orbit (obtained like the latitude of its Rising point) and doing (i).

19. **The Drkkshepajya related to the Sun (Sine Zenith distance of the Nonagesimal)** and the corresponding **Drkkshepajya related to the Moon.** Multiply the Madhyajyā of each by the respective Udayajyā and divide by Trijyā. Square this and deduct from the square of the respective Madhyajyā. The root of the remainder will be the respective *Dṛkkṣepajyā*.

20-22. **The Drgjya (Sine Zenith distance) of the Sun and the Moon.** The Sun's Dṛgjyā is got according to III. 18-20 from the desired time. The Moon's Dṛgjyā is to be got in the same way, using the declination of the Moon, and the other elements like Dyujyā, Kṣitijyā and Cara derived from it. The declination of the Moon is got by combining its latitude and the declination derived from its longitude, taking into consideration their directions.

23. **The Drggatijya related to the Sun and the Moon.** The square root of the difference between the squares of the respective Dṛgjyā and Dṛkkṣepajyā is the respective *Dṛggatijyā*.

Note. The use of the word *Dṛggatijyā* here is to be distinguished from its use in other works like the *Sūryasiddhānta.*

24. **Parallax in longitude (Lambana).** The respective Dṛggatijyā multiplied by the radius of the Earth and divided

by the respective Radius Vector gives the respective *Lambana* or Parallax in longitude in minutes of arc.

25. **The Time of Conjunction in longitude, as corrected for Parallax.** Find the difference of the two parallaxes and multiply by 60. Divide by the difference between the daily motions of the Sun and the Moon. Deduct the resulting nāḍis from the time of Conjunction (*Amānta*) if forenoon, and add if afternoon. The result will be the *Parallax-corrected Conjunction.*

26. **Application of the Parallax in time when the Conjunction is at midday.** If the Madhyajyā of the Moon and its Udayajyā are of the same direction the time is to be deducted, otherwise added.

Note 1. There are certain errors of omission and commission here, which are tackled in the *Bhāṣya* and the *Siddhāntadīpikā.*

Note 2. The use of the word *Titheḥ* here shows that the *Siddhāntadīpikā's* interpretation of *Dinārdhakāla* in '*Athavā dīnārdhakālaśuddhena etc*'. is plausible, thereby saving Bhāskara from one error at least.

27. **The Correct Parallax-corrected Conjunction by successive approximation.** Use the Corrected Conjunction found by verse 25 as Conjunction and repeat the operation, with the Sun, the Moon etc. of those times. The Correct Corrected-conjunction is got. Find the Sun and Moon at this time.

28-30a. **The Relative Parallax in latitude (Avanati-lipta).** Take the Dṛkkṣepajyās of the Sun and the Moon last obtained in using verse 27. Multiply by the radius of the Earth and divide by the respective Radius Vector. The result is the respective Parallax in latitude and its direction is that of the respective Madhyajyā. If of the same direction subtract one from the other, and if of opposite directions add. This is Relative Parallax, and its direction is that of the Moon's parallax.

30a-31. **Correction of latitude for Parallax (Nati-Samskara).** Deduct the Moon from the Ascending Node and get its sine; multiply it by 270 and divide by the True hypotenuse in minutes. This is the True latitude. Add the True latitude and Relative parallax if of the same direction, and take the difference if of different directions. The result is the Parallax-corrected Latitude (*Vikṣepa-samskṛtā Nati*).

32. **True Parallax in latitude (Sphuta-Nati)** and its application. The Parallax-corrected Latitude got in 28-31 refers to the middle of the eclipse, and so only the approximate beginning and end can be got from it. What is to be done to get the correct beginning and end, is given here. The difference in parallax (in longitude) between the beginning and middle, as also the difference related to the middle and end, is to be applied to the first and second half-durations respectively. From the corrected times the work of 28-31 is to be done separately, to find the correct beginning and end.

33. **Occurrence or non-occurrence of Eclipse.** Deduct from the angular diameter (*liptā-vyāsa*) of the Sun 1/8th of itself, and add the angular diameter of the Moon. Divide by 2. Call the result D. If the Parallax-corrected latitude related to the middle of the eclipse (say λ) is less then D, only then will there be an eclipse.

34. **The Half-duration of the Eclipse (Sthityardha).** Find $\sqrt{(D^2-\lambda^2)}$. Multiply this by 60 and divide by the difference of the daily motions of the Sun and Moon. The nāḍikās got is the Half-duration or *Sthityardha*.

35-39. **The Beginning and End of the Eclipse (Sparsa and Moksa).** The Corrected time of Conjunction *minus* or *plus* the Half-duration gives the (rough) Beginning and End of the eclipse. (The Corrected Conjunction is the Middle). Using these times separately the Dṛkkṣepa, Dṛggati etc. are to be got, and through them the respective parallaxes in time. The difference between the parallax related to conjunction and that related to the beginning is to be added to the Half-duration, which is to be subtracted from the Corrected conjunction to get the True beginning. The difference between the parallax related to Conjunction and that related to the End is to be added to the Half-duration, which is to be added to the Corrected conjunction to get the True end. This is the general rule. If the Beginning and Middle are, one in the forenoon and the other in the afternoon, then the Parallax in time due to the Beginning should all be added to the Half-duration to be deducted to find the True beginning. If the Middle and the End are one in the forenoon and the other in the afternoon, then also the Parallax in time due to the End should all be added to the Half-duration to find the True end. This rule applies when the Middle falls at midday also.

by the respective Radius Vector gives the respective *Lambana* or Parallax in longitude in minutes of arc.

25. **The Time of Conjunction in longitude, as corrected for Parallax.** Find the difference of the two parallaxes and multiply by 60. Divide by the difference between the daily motions of the Sun and the Moon. Deduct the resulting nāḍis from the time of Conjunction (*Amānta*) if forenoon, and add if afternoon. The result will be the *Parallax-corrected Conjunction.*

26. **Application of the Parallax in time when the Conjunction is at midday.** If the Madhyajyā of the Moon and its Udayajyā are of the same direction the time is to be deducted, otherwise added.

Note 1. There are certain errors of omission and commission here, which are tackled in the *Bhāṣya* and the *Siddhāntadīpikā.*

Note 2. The use of the word *Titheḥ* here shows that the *Siddhāntadīpikā's* interpretation of *Dinārdhakāla* in '*Athavā dīnārdhakālaśuddhena etc*'. is plausible, thereby saving Bhāskara from one error at least.

27. **The Correct Parallax-corrected Conjunction by successive approximation.** Use the Corrected Conjunction found by verse 25 as Conjunction and repeat the operation, with the Sun, the Moon etc. of those times. The Correct Corrected-conjunction is got. Find the Sun and Moon at this time.

28-30a. **The Relative Parallax in latitude (Avanati-lipta).** Take the Dṛkkṣepajyās of the Sun and the Moon last obtained in using verse 27. Multiply by the radius of the Earth and divide by the respective Radius Vector. The result is the respective Parallax in latitude and its direction is that of the respective Madhyajyā. If of the same direction subtract one from the other, and if of opposite directions add. This is Relative Parallax, and its direction is that of the Moon's parallax.

30a-31. **Correction of latitude for Parallax (Nati-Samskara).** Deduct the Moon from the Ascending Node and get its sine; multiply it by 270 and divide by the True hypotenuse in minutes. This is the True latitude. Add the True latitude and Relative parallax if of the same direction, and take the difference if of different directions. The result is the Parallax-corrected Latitude (*Vikṣepa-samskṛtā Nati*).

32. **True Parallax in latitude (Sphuta-Nati) and its application.** The Parallax-corrected Latitude got in 28-31 refers to the middle of the eclipse, and so only the approximate beginning and end can be got from it. What is to be done to get the correct beginning and end, is given here. The difference in parallax (in longitude) between the beginning and middle, as also the difference related to the middle and end, is to be applied to the first and second half-durations respectively. From the corrected times the work of 28-31 is to be done separately, to find the correct beginning and end.

33. **Occurrence or non-occurrence of Eclipse.** Deduct from the angular diameter (*liptā-vyāsa*) of the Sun 1/8th of itself, and add the angular diameter of the Moon. Divide by 2. Call the result D. If the Parallax-corrected latitude related to the middle of the eclipse (say λ) is less then D, only then will there be an eclipse.

34. **The Half-duration of the Eclipse (Sthityardha).** Find $\sqrt{(D^2-\lambda^2)}$. Multiply this by 60 and divide by the difference of the daily motions of the Sun and Moon. The nāḍikās got is the Half-duration or *Sthityardha*.

35-39. **The Beginning and End of the Eclipse (Sparsa and Moksa).** The Corrected time of Conjunction *minus* or *plus* the Half-duration gives the (rough) Beginning and End of the eclipse. (The Corrected Conjunction is the Middle). Using these times separately the Dṛkkṣepa, Dṛggati etc. are to be got, and through them the respective parallaxes in time. The difference between the parallax related to conjunction and that related to the beginning is to be added to the Half-duration, which is to be subtracted from the Corrected conjunction to get the True beginning. The difference between the parallax related to Conjunction and that related to the End is to be added to the Half-duration, which is to be added to the Corrected conjunction to get the True end. This is the general rule. If the Beginning and Middle are, one in the forenoon and the other in the afternoon, then the Parallax in time due to the Beginning should all be added to the Half-duration to be deducted to find the True beginning. If the Middle and the End are one in the forenoon and the other in the afternoon, then also the Parallax in time due to the End should all be added to the Half-duration to find the True end. This rule applies when the Middle falls at midday also.

Note. A possible error in these instructions is discussed in the *Bhāṣya* under 39b and is sought to be rectified by the *Siddhāntadīpikā*.

40. **Total Eclipse.** Find the difference between the angular diameters and divide by 2. Call this D'. If λ is less than D' there is Total eclipse if the Moon's angular diameter is greater than the Sun's. (If the angular diameter of the Moon is less than that of the Sun, there is only Annular eclipse). Find $\sqrt{(D'^2-\lambda^2)}$, and from this the duration of the Total eclipse as before.

Note. The distinction between Total and Annular eclipse is not made in the Text or the commentaries. The *Bhāṣya* takes the text to mean only Total eclipse by stating: *grāhyabimbārdhona -grāhakabimbārdha-tulyam.*

41. **The Correction for the Brightness** of the Sun already adopted in 33-34 is here given. Find the time of the Half-durations proportionate to the eighth part of the angular diameter of the Sun. Add this to the time of Beginning (and subtract from the time of End) to get the Visible Beginning (and End).

42-47. For the proper **Orientation of the Eclipse in Graphical representation** and prediction of the first and last points of contact etc. the bending (*valana*) of direction due to : (i) the latitude, ϕ. of the place (*Ākṣa-valana*), (ii) the position on the Ecliptic (*Āyana-valana*), and (iii) the Corrected latitude of the Moon, λ, are to be taken into account.

(i) **Aksha-valana** is given by 42-44. Find the time interval between midday and the Beginning, the End and the Middle, severally and convert it into degrees. Find the versine (*utkramajyā*) of this, Multiply this by Sin ϕ and divide by Trijyā. Find its arc. This is ***Ākṣa-valana.*** If the converted degrees are greater than 90, take the excess over 90, find its sine, add this to Trijyā, and do the multiplication by Sine ϕ etc. If the time is before midday, the *valana* or bending of the eastern part of the eclipsed body is northwards and of the western part, southwards. If the time is afternoon, the *valana* is opposite to what is mentioned.

(ii) **Ayana-valana** is given by verse 45. Add 3 rāśis to the Sun (or Moon in the case of the lunar eclipse) and find its versine.

Multiply this by 1397, divide by Trijyā and get the arc. This is the *Āyana-valana*. The direction of this *valana* in the eastern part is northwards or southwards according to the *ayana* (*i.e*. the northward or southward course) of the eclipsed body. In the western part it is vice versa.

(iii) **Combination of Akshavalana and Ayanavalana with the Corrected latitude.** If the two valanas are of the same direction add them; if of different directions, deduct one from the other and take the direction of the greater. Find its sine, multiply by half the sum of the angular diameters and divide by Trijyā. This is *Reduced Valana*. Add this to the latitude if of the same direction; subtract one from the other if of different directions, and take the direction or the greater. Call this 'Combined Minutes.' (In the case of the lunar eclipse the direction of the latitude is to be taken as opposite to what it is (*cf*. verse 58) and the work done as above.) In the case of the Middle of the eclipse there is no combination of *Valana* with latitude.

> *Note*. The impropriety of using the versine in valana is mentioned in an editiorial footnote under verses 46-47.

48-67. **Graphical representation of Eclipses.** (i) 48-53 give the preliminary work, and points of first and last contacts. (ii) 54-57 give the 'Midde point'. (iii) 58 gives the peculiarity in the Lunar eclipse in the matter of applying valana. (iv) 59-60 give the representation of the Middle of the eclipse. (v) 61 gives the manner of tracing the path of the eclipsing body. (vi) 62-63 give the theoretical determination of the part eclipsed, at any desired time. (vii) 64-65 give its representation in the figure. (viii): 66-67 give the positions of immersion and emergence in the case of the Total eclipse.

(i) 48-53. **Preliminary work and first and last Points of contact.** The scale is half an aṅgula per minute of arc, or any scale agreeing with the appearance in the sky. Using a pair of compasses draw on the floor a circle of radius equal to the semi-diameter of the eclipsed body. Concentric with this draw another circle with radius equal to the sum of the semi-diameters of the eclipsing and eclipsed bodies. Draw the E-W lines. Mark the 'Combined Minutes' (got in verse 47) according to its direction, on the N-S line, from the centre, and draw the horizontal line passing through the point towards the beginning or ending side, whether east or west. From the

point where it meets the outer circle, draw a straight line to the centre. Where the line cuts the inner circle is the first or last point of Contact.

(ii) 54-57. **Middle point (Madhya-bindu).** As regards the representation of the Middle of the eclipse, take the latitude not corrected by Reduced valana. If the Reduced valana (related to the west of the eclipsed body) and the latitude are of the same direction, mark a point equal to the Reduced valana towards the east of the centre; if of different directions, mark the point towards the west. Through that point draw the vertical line to meet the outer circle in the direction of the latitude. Draw the line joining the meeting point and the centre, and on this mark a point of distance from the centre equal to the latitude. This is the centre of the eclipsing body at the Middle of the eclipse. This is the *Middle point* (*Madhyabindu*).

(iii) 58. **Application of Valana in the Lunar eclipse.** In the case of the lunar eclipse if the latitude is north, take it as south and vice versa, and do the work of (i) and (ii). (In fact this has been mentioned already).

(iv) 59-60. **Middle of the eclipse (Grahana-madhya).** With the 'Middle point' as centre draw a circle of radius equal to that of the eclipsing body. As it cuts the eclipsed body, or as the eclipsed body is completely immersed in it, all this will be seen in the sky exactly as represented on the floor, at the Middle of the eclipse.

(v) 61. **The Path of the eclipsing body (Grahaka-marga).** Draw the circle passing though the three points got in (i) and (ii). This is the path of the eclipsing body.

(vi) 62-63. **The part eclipsed at any time (Ishtagrasa).** Deduct the desired time in nāḍis after the beginning (or before the end), from the respective half-duration. Multiply by the difference of the daily motions of the Sun and the Moon and divide by 60. Square this and add the square of the Parallax-corrected latitude (*Avanati*). Find the root. This is the distance between the bodies at the desired time. This deducted from D (of verse 33) is the part eclipsed at that time.

(vii) 64-65. **Representation of the part eclipsed.** Take a slender bamboo strip equal in length to the result of (vi), *i.e.* the

distance between the bodies at the desired time. Lay it in the figure with one end at the centre and the other contacting the path found by (v). This can be done in two ways. With the points of contact as centre draw circles of radius equal to the semi-diameter of the eclipsing body. This represents the eclipse at those times exactly as seen in the sky.

(viii) 66-67. **The immersion and emergence in Total eclipse (Sarvagrasa).** On the path of the eclipsing body, mark the two points on either side of the 'Middle point' corresponding to the times of immersion and emergence (which will be at distance equal to the difference of the semi-diameters from the centre of the eclipsed body). With these points as centres and with radius equal to the eclipsing body, draw two circles. Where the eclipsed body touches these circles, are the points of immersion and emergence.

The Lunar Eclipse

68-70. The author asserts that parallax correction should be done in the case of the Lunar eclipse also, with the following changes : In the place of the Sun, the Shadow, *i.e.* the Sun *plus* six rāśis, is to be used. The Radius Vector of the Moon is to be used in getting the Parallax in longitude or latitude of the Shadow also, and when these exceed those of the Moon, the addition and subtraction (for relative parallax) are to be reversed.

Note 1. It is pointless to do the Correction for Parallax in the lunar eclipse. This can be shown in two ways : (i) The Moon being hidden or not hidden by the Shadow has nothing to do with the position of the observer (upon which parallax depends). So if an observer at the centre of the earth, to whom there can be no parallax, sees the Moon eclipsed, the man situted on the surface, and has the Moon even on the horizon so as to have the maximum parallax, must also see the Moon eclipsed, so that parallax in no way affects it. (ii) Any point on the Moon's surface is depressed by parallax by exactly the same extent as the point in the Shadow with which it coincides, so that there can be no difference in parallax to be used for correction. What appears to be a difference is spurious, and is due to not doing the work in the strictly proper manner

i.e. from point to point, but taking the parallax of the centre of the Moon for the parallax at every point on the Moon, and taking the parallax of the centre of the Shadow for that at every point on the Shadow.

Note 2. The *Siddhāntadīpikā* attempts to save Bhāskara by saying that he is giving the opinion of some other school of Astronomers, and it is not his own. But Bhāskara cannot be thus saved because it is against his own statement in 74a below.

71-73. **The Computation of the angular diameter of the Shadow (Chaya-lipta-vyasa).** Multiply the Radius Vector of the Sun by the diameter of the Earth and divide by the difference of the diameters of the Sun and the Earth. The result is the length of the Shadow cone. Or (because the Earth's diameter ÷ the difference of the diameters = 5/16), multiply the Radius Vector of the Sun by 5 and divide by 16 to get the length of the Shadow cone. Deduct the Radius Vector of the Moon from this. Multiply by the diameter of the Earth and divide by the length of the Shadow cone. Again multiply by Trijyā and divide by the Radius Vector of the Moon. The result is the angular diameter of the Shadow.

74a. Bhāskara says that some astronomers do not advocate parallax correction in the lunar eclipse, thereby showing that what he has already given in 68 is his view, and not the one given here.

74b-76. **The Half-duration of the eclipse** is found by using the latitude at the Middle of the eclipse as λ in the first instance. By successive approximation using the latitude of the beginning and end of the eclipse, the correct times of the beginning and end are to be computed. The latitude at the beginning and end are to be got by getting the Moon's longitudes at the beginning and end, thus: Multiply the daily motion of the Moon by the times of half-durations in nāḍis and divide by 60. The minutes got are to be subtracted or added according as the Moon at the beginning or end is sought. The Half-duration of the total obscuration also is to be got in the same way.

77. In the graphical representation, if the latitude is north it should be taken as south and used, and vice versa. (This has been referred to already under 48-67, iii).

Note. The *Siddhānta-dīpikā* here gives a regualr treatise on the theory of eclipses in about 100 ślokas. Incidentally valuable information about several solar and lunar eclipses which Parameśvara had observed, are given here.

78. Conclusion.

CHAPTER VI

Miscellaneous things like the Heliacal Rising of the Moon, the Phases of the Moon, the Moon's Graphical representation and the Horns of the Moon, the Time of Moonrise and Upper Culmination, the Heliacal Rising of the Star-planets and their Conjunction, Latitude and Occultation, are given in this chapter.

1-4a. Two corrections, (i) **Aksha-drkkarma** and (ii) **Ayana-drkkarma**, to the Moon and the Star-planets, required to compute their Heliacal rising and setting (*udayāsta*) are here given.

(i) **Aksha-drkkarma (Reduction for observation due to the latitude of the observer)**. Multiply the Moon's (and the Star-planet's) latitude by Sine ϕ and divide by Cos ϕ. The result is to be subtracted from the Moon's (or Star-planet's) True longitude if its latitude is north and it is rising, and added if it is setting. If the latitude is south, the addition and subtraction are to be interchanged.

(ii) **Ayana-drkkarma (Reduction for observation due to position on the Ecliptic)**. Deduct 3 rāśis from the Moon (or the Star-planet) and find its Versine. Multiply this by 1397, and by the latitude of the body in minutes, and divide by the square of Trijyā. This is to be deducted from the True longitude if the *ayana* of the body and its latitude are of the same direction, and added if of opposite directions.

These Dṛkkarma corrections are to be made only in the matter of rising and setting of the planets and nowhere else.

Note 1. The use of Versine in (ii) is wrong and deprecated by astronomers like Bhāskara II (*vide Siddhānta Śiromaṇi*, Gola., Dṛkkarmavāsanā, 16). They are referred to in the *Siddhāntadīpikā* by Parameśvara with the

reference '*kaiścit sudhībhiḥ*', and another method is given in 19 verses.

Note 2. The *Siddhāntadīpikā* rightly shows also that correction for parallax, used by some astronomers in the matter of the heliacal rising and settting of the Moon and the Star-planets, is wrong.

4b-5a. **The Condition for the Moon's Heliacal rising and setting.** Find the difference between the Sun and Moon corrected by Dṛkkarma. Convert this into time using the Oblique Ascensional difference. When this is 2 nāḍis the Moon is visible; (*i.e.* if the Moon does not set within 2 nāḍis after sunset, or does not rise within 2 nāḍis before sunrise, it will be visible).

5b-7. **The fraction of the Moon lighted up by the Sun (Sitabhaga).** Take the Moon *minus* Sun in longitude. If it is within 3 rāśis, take its Versine. If between 3 rāśis and 6 rāśis deduct 3 rāśis and take its Sine and add Trijyā to it. Multiply the Moon's angular diameter by this and divide by 6876 (*i.e.* twice Trijyā). The result is the part lighted up, in minutes. If Moon *minus* Sun is more than 6 rāśis, deduct 6 rāśis and do the work as above; but here the result is the part of the Moon not lighted up. If this is subtracted from the angular diameter, the lighted up part is got.

8. **The Moon's Declination and Declinational Ascensional difference (Chandrapama and chara).** Add the Moon's latitude to the Declination due to its longitude, if they are of the same direction; subtract one from the other if they are of opposite directions, and take the direction of the latter. This will be the True Declination of the Moon. From the sine etc. of this find the *Cara* of the Moon.

9-12. **(i) The Moon's Great Gnomon (Chandra-Mahasanku).** Compute the True longitude of the Sun and the Moon at sunset (or required time). From this, using the Right Ascensional differences of the Setting Sign, the next Sign etc., compute the Hour-angle equal to the longitude difference of the Sun and the Moon. Using the Hour-angle and the Moon's Cara, Dyujyā and Kṣitijyā, (got in verse 8), find the Moon's Great Gnomon as in the case of the Sun.

(ii) The Moon's Sankvagra. Multiply the Moon's G.G. by Sin ϕ and divide by Cos ϕ. The result is the Moon's Śaṅkvagra. It is always south.

(iii) **The Moon's Agra (Sine Amplitude).** Multiply Sin declination of the Moon (got in verse 8) by Trijyā and divide by Cos ϕ. The Moon's Agrā is got. Its direction is that of the Declination.

(iv) **The Moon's distance from the Prime Vertical.** Add the Śaṅkvagra and Agrā if of the same direction and take that direction. Deduct one from the other if of different directions, and take the direction of the greater. This is the N-S distance of the Moon from the Prime Vertical.

(v) **The Moon's Bhjua (Base) and Koti (Perpendicular).** If the Sun's Agrā is north take it as south and vice versa, and apply this also to (iv) in the same manner as mentioned therein. This is called the "Base". The G.G. got in (i) is called the "Perpendicular."

These are for use in the graphical representation below.

13-17. **The Graphical Representation at Sunset.** Lay the "Base" North or South, according to its direction, from the Sun. From the end of the "Base" lay the "Perpendicular" east or west (in this case eastward). Draw the hypotenuse to meet the end of the Perpendicular. At this meeting point draw the Moon, using its angular semidiameter. Take the hypotenuse as the E-W of the Moon and draw the N-S, *i.e.* draw the perpendicular to the hypotenuse through the centre of the Moon and take the two points cutting the orb. Along the hypotenuse lay the minutes of the lighted part, found in verses 5b-7, from the point where the hypotenuse enters the Moon, and mark the point. Draw the arc of the circle passing through the three points. The part between the Sun-ward rim and this arc is the lighted part. From this, the depression, elevation or horizontalness of the horns of the Moon are all seen in the sky as in the graphical representation.

18-19. **Graphical representation for other times.** At times other than sunset the G.G. etc. are to be computed using as before the *Asta-lagna* (Setting point of the ecliptic), and the longitude of the Moon at that time, and the work done.

If the elongation of the Moon is more thand 90°, use the *Udaya-lagna* instead of the *Asta-lagna*, as the Sun in the above work, and find G.G. etc. In this case instead of the measure of the lighted part use the measure of the unlighted part (*i.e.* the angular diameter of the Moon *minus* the lighted part).

20. In computing the Hour-angle (*Natabhāga*) for work in verses 9-12, or subsequent similar work, the method of successive approximation is not to be used.

21. Till the end of the light fortnight this work of the Moon is to be done by using the Sun, the Moon, and the Ascending Node at sunset, in the manner that has been mentioned.

22. **The Time-interval between sunset and moonrise on the full-moon day.** Find the interval in time corresponding to the difference in longitude of the Sun and the Moon at sunset. Find the difference between this and the daytime. By so much time the Moon rises earlier than sunset, if the daytime is greater, later if less.

Note. The method of successive approximation is to be used here.

23-26. **The Representation of the Moon above the eastern horizon in the dark fortnight.** The representation is done using the G.G. etc. got from the Rising ecliptic point at the desired time, inclusive of sunrise. Here the "Perpendicular" is westward. But the "Base" is as before, only N-S. The hypotenuse is as usual. From the east the minutes of the lighted part is to be laid in the Moon's orb; or from the west the minutes of the unlighted part is to be so laid.

The Duration of the visibility of the Moon (Drsya-kala)

Note. (From this duration the time of moonrise can be computed, as also moonset). In doing the following work the Sun and the Moon should be taken corrected for Parallax, and the Moon corrected for *Dṛkkarma* also.

27. **Duration of visibility in the light fortnight.** Add 6 rāśis to the Sun and the Moon at sunset. From their difference in longitude find the interval in time, using the corresponding Oblique Ascensional difference. Adding this time to sunset find the Sun and the Moon at that time, and repeat the work. Thus the most correct time is got by successive approximation, and so long the Moon is visible.

28. **Duration of visibility in the dark fortnight.** Add 6 rāśis to the Sun alone and do the work in verse 27. By so much time after sunset the Moon rises in the night. The difference between this and night-time is the duration of visibility.

29-31. **Alternative method for the above.** Using the method of verse 27 find the interval in time between the *Udaya-lagna* and the Moon at sunset. Apply this time to sunset as mentioned hereunder. Find the *Udaya-lagna* and the Moon at this time and repeat the operation a sufficient number of times. Apply the time got to sunset. The time of moonrise is got. When the time-interval is applied to sunset it should be added if the (Parallax and Dṛkkarma corrected) Moon is greater than the *Udaya-lagna*, and subtracted if less.

Note. The *Siddhānta-dīpikā* here quotes an alternative interpretation giving a slightly different method.

32-36. **Another alternative method for (28).** Take the Sun and Moon at sunset. Find the interval in time between the Sun and the Moon, using the Oblique Ascentional difference of the place. Deduct the daytime from this. Add the remainder to sunset. The time of moon-rise is got. This time also should be made correct by successive approximation. It should be done thus : The motion of the Sun and the Moon during the time from sunset up to the time of rise of the moon should be added to the Sun and Moon, at sunset, and the work repeated as many times as necessary. If the daytime is longer than the interval in time, deduct this from the daytime. By so much time before sunset the Moon rises. Here too successive approximation is to be done as before, but instead of adding, the motion of the Sun and the Moon should be deducted from the Sun and Moon at sunset.

37-38. What can conveniently be done when the dark fortnight is so advanced that the end of the lunar month is near, is given here. The Moon and Sun at sunrise are to be found, and the interval in time taken using the Oblique ascensional difference; and this is to be corrected by successive approximation, deduction of the motions being done. By so much time before sunrise the Moon rises.

39-41a. **The time when the Moon reaches the Meridian (*i.e.* Upper Culmination) and the Moon then.** Take any time near the time of the Moon reaching the meridian. Find the Moon and the Meridian point of the ecliptic at that time. Using the Right ascensional difference find the interval in time between them. If the moon is greater add the interval in time to the taken time, and vice versa. This is the first approximate time. Use this as time taken. Find

the Moon then and repeat the operation as often as necessary. The Moon at the meridian, and its time, are got.

41b. From the above the Moon's latitude and the declination due to the Moon's longitude, and thereby its True declination can be found. From this and the latitude of the place the Meridian Zenith distance, and therefrom its Sine, can be found.

42. **The Elevation of the Moon's horn (Srngonnati) at moon-rise or moon-set.** At moon-rise or moon-set the horn on that side is elevated on which side, north or south, the Sun is, which is found by (9-12). (But here, as the Sun is below the horizon, the G. G. of the Sun in the night is to be used for Śaṅkvagra, which is to be taken as north).

43. **The case of the Star-planets.** All this work pertaining to the Moon, *viz.* the Heliacal rising, the phases, the elevation of the horns, rising and setting and upper culmination (*i.e.* reaching the meridian), apply to the Star-planets as well, with slight differences.

44-47. **Heliacal rising of the Star-planets.** When the several planets are distant from the Sun as follows — Venus by 9°, Jupiter by 11°, Mercury by 13°, Saturn by 15° and Mars by 17°, of time,—they will be visible. Venus in retrograde motion will be visible owing to its great brightness at 4½° or 4° of time from the Sun. Multiply the degrees of time by 10. The corresponding vināḍis are got. When the setting and rising pertain to the east take the Oblique ascensional difference of the Rāśi of the planet, and when they pertain to the west, take the Oblique ascensional difference of the seventh Rāśi counting from it. Multiply the difference in degrees between the planet and the Sun by the taken ascensional difference and divide by 30; the result is time. When this time is equal to the corresponding vināḍis got above, the Heliacal rising (or setting) takes place.

48. **Distance between the Earth and the Star-planets in minutes of arc (Graha-bhumyantara-lipta-pramana)** is got by multiplying the Manda-karṇa by the Śīghra-karṇa and dividing by Trijyā. This is the "divisor" used in the computation of the latitude of the Star-planets.

49-51. **Computation of the Conjunction of Planets (Samalipti-karana).** Divide the difference between the longitudes of the two planets by the difference of their daily motions if the motions are

both direct or both retrograde, and by their sum if otherwise. The time got is days etc. This should be added to the taken time if the faster planet is less. (Note that any direct motion is faster than retrograde motion. The lesser retrograde motion is taken as faster than the greater retrograde). Otherwise it should be subtracted. The Time of Conjunction (*samaliptā*) is got. As the motion is always changing, a better result will be obtained by taking this time and repeating the work, and so on.

52-55. **Computation of the latitude of planets (Vikshepanayana).** Find the True planet at Conjunction. Deduct the Ascending Node from it and get its sine. Multiply the Maximum latitude (*parama-vikṣepa*) (given in VII. 9) by this, and divide by the " divisor" got in verse 48 (*i.e.* the distance between the Earth and the Star planet in minutes). The latitude of Jupiter, Mars and Saturn are thus got. In the case of Mercury and Venus, use their Śīghrocca at conjunction and do the work. The latitude is north if the remainder after deducting the Ascending Node is within 6 rāśis, and south if more. If the latitude of the two planets in conjuction are of the same direction find their difference ; if of different directions, add them. The result is the distance between them. The distance is to be calculated at $\frac{1}{4}$ angula per minute or $\frac{1}{2}$ angula per minute according as it would appear in the sky, and predicted.

Note. The use of the True longitude (at conjuction) for latitude in the case of Mars, Jupiter and Saturn is worng. The use of the Śīghra in the case of Mercury and Venus is very rough. The *Siddhāntadīpikā* notes this and gives the correct method.

56. **The Mean angular diameters of the planets**, in minutes are: Venus 32/5, Jupiter 32/10, Mercury 32/15, Saturn 32/25 and Mars 32/25.

57-58a. **The Distance of the Planets from the Earth** for the sake of getting the divisor in computing Parallax etc: Multiply the radius of the Moon's orbit in yojanas by 5, 10, 15, 20, 25; the respective mean distances are got. Multiply this by the "divisor" got in (48) and divide by Trijyā, The True distance or divisor to compute parallax etc. of the planets is got.

58b. **The True angular diameters of the Planets.** The mean angular diameters got in (56) multiplied by Trijya and divided by the "divisor" (in 48), will give the True angular diameters.

59. The Latitudes of the Rising and Meridian Points of the planets' Orbits for use in the calculation of the Ten Sines (*Daśajya*): Deduct the planet's Ascending Node from the Rising and Meridian points of the ecliptic, find its sine, and multiply the respective Maximum latitude (given in VII. 9) by this. Divide the result by the "divisor" (in 48). The latitudes of the Rising and Meridian points of the planets' orbits are got.

60-61. **The rest of the work for the Computation of Occultation,** *viz.* direction etc. The "Ten Sines" are to be done as in the case of the Moon using the respective *cara* (*i.e.* Declinational ascensional difference). The G.G. is to be got. In the matter of computiug the Parallax in longitude and latitude, the respective divisor for parallax (got in 57-58a) is to be used. The rest of the work, like the Half-duration etc. are to be done as instructed in the case of eclipses.

62-63. Conclusion.

CHAPTER VII

This chapter contains in verses 1-16, 20, the Astronomical Constants required for work in the rest of the book, like the revolutions of the planets, epicycles etc. Incidentally in verses 21-35 the constants of the *Ārdharātrika system* of Āryabhaṭa (which are the same as those of the *Saura-Siddhānta* of the *Pañcasiddhāntikā* and as those of the *Khaṇḍakhādyaka* of Brahmagupta) are given, as also its difference in methods. A method is given in 17-19 to do computations without using the Tabular Sines.

1-5. The Number of Revolutions of the Planets etc. In a *Mahā-yuga* the cycles of the Mean Sun, Mercury and Venus are 43,20,000; of the Mean Moon 5,77,53,336; of Mean Saturn 1,46,564; of Mean Jupiter 3,64,224; of Mean Mars 22,96, 824; of the Moon's Higher Apsis 4,88,219 · of the Moon's Ascending Node (*i.e. Rahu*) 2,32,226; of the Apsis of Conjuction (*Sīghra*) of Mercury 1,79,37,020; of the *Śīghra* of Venus 70,22,388; and of the *Śīghra* of Saturn, Jupiter and Mars 43,20,000.

6-8, **The Intetcalary Months (Adhimasa)** in a Mahā-yuga are 15,93,336, and the divisor to obtain the intercalary moths gone (*i.e.* the Solar months) are 5,18,40,000. The *omitted Lunar days*

(*Avama*) are 2,50,82,580, and the divisor to obtain the Omitted lunar days gone (*i.e.* the *Yuga Tithis*) are 1,60,30,00,080. The number of *Civil Days* (*Bhūdina*) are 1,57,79,17,500.

9-10. **Maximum (Mean) Latitudes of planets (Parama-vikshepa).** The maximum (mean) latitude of Mercury, Venus and Saturn is 2 degrees, of Jupiter 1 degree, and of Mars 1½ degrees. The *Longitudes of their Ascending Nodes* are : Mercury 20°, Venus 60° Saturn 100°, Jupiter 80° and Mars 40°. If the remainder of the longitude after deducting the Ascending Nodes is within 6 rāśis, the latitude is North; if more than 6 rāśis, the latitude is South.

11-12. **The Longitudes of Mandocca, i.e. the Higher Apsis,** pertaining to the Equation of the Centre, are : Mercury 210°, Venus 90°, Saturn 236°, Jupiter 180°, and Mars 118°. Of the Sun it is 78°. (And of the Moon it is given above in 1-5). In getting the Anomaly for computation, the Mandocca is always to be deducted from the Mean longitude, and the Mean longitude is to be deducted from the Śīghra.

13-16. **The Epicycles of the Equation of the Centre (Manda-paridhi)** of the planets are: Mercury 7° - 5°, Venus 4° - 2°, Saturn 9°-13°, Jupiter 7° - 8° and Mars 14° - 18°, the first of each diad being related to the odd quadrants and the second to the even quadrants. The epicycle of the Equation of the Centre of the Sun is 3° and of the Moon 7°.

The Epicycles of the Equation of Conjunction (Sighra-paridhi) are: Mercury 31°- 29°, Venus 59° - 57°, Saturn 9° - 8°, Jupiter 16° - 15°, and Mars 53° - 51°, for the odd and even quadrants respectively. (It is to be noted that all epicycles have been divided out by 4½, and therefore the divisor is 80 and not 360).

The Tabular Sine intervals, 225, 224, 222 etc. given by Āryabhaṭa in *Gītikā* 10 are to be used in computations.

17-19. **A Method for Computation without Tabular Sines.** (i) Take the Bhujāṁśa for which the Phala is wanted. Deduct the Bhujāṁśa from 180 and multiply the remainder by the Bhujāṁśa itself. (ii) Deduct (i) from 40,500 and divide the result by 4. (iii) Multiply (i) and the Antyaphala (*i.e.* Maximum equation) and divide by (ii). The result is the *Bhujā-phala*. If instead of Bhujāṁśa, the

Koṭyaṁśa is used the *Koṭi-phala* will be got. If *Utkramajyā-phala* is wanted the degrees for which it is wanted are deducted from 90°, and this used in the formula. The final result, here, is to be deducted from Antyaphala. The *Utkramajyā-phala* is got.

20. **The Circumference of the Celestial Sphere in yojanas is got by multiplying the Moon's cycles, 5,77,53,336, by 2,16,000. This divided by the cycles of the desired planet gives the Circumference of the planet's orbit.**

The Ardharatrika System of Aryabhata

21. What has hitherto been given is according to Āryabhaṭa's *Audayika system* (which takes the day to begin at sunrise), given in the Āryabhaṭīya. The Ślokas that follow give Āryabhaṭa's *Ārdharātrika system* (where the day is taken to begin at midnight). Where there is no difference mentioned, both the systems are to be taken as having the same constants and methods.

22. Add 300 to the civil days to get the civil days of the Ārdharātrika system. Subtract 300 from the Omitted lunar days. Deduct 20 from the cycles of the Śīghra of Mercury. Deduct 4 from the cycles of Mean Jupiter.

23-24. The diameter of the Earth is 1600 yojanas, of the Sun 6480, and of the Moon 480. The radius of the Sun's orbit is 6,89,358, and of the Moon's 51,566 yojanas.

25-28a. The longitudes of the Higher Apses pertaining to the Equation of the Centre (*Mandocca*) are : of Mercury 220°, Venus 80°, Saturn 240°, Jupiter 160°, Mars 110°, and of the Sun 80°. The Epicycles pertaining to the Equation of the Centre (*Manda-paridhi*) are: Mercury 28°, Venus 14°, Saturn 60°, Jupiter 32°, Mars 70°, Sun 14° and Moon 31°. (Note that these are not divided out by 4½ and so the divisor is 360. Also no distinction is made between odd and even quadrants.) The epicycles pertaining to the Equation of Conjunction (*Śīghra-paridhi*) are: Mercury 132°, Venus 260°, Saturn 40°, Jupiter 72° and Mars 234°.

28b-33. Each Star-planet has two Ascending Nodes called *Manda-pāta* and *Śīghra-pāta*, excepting Mercury which has only *Manda-pāta*. They are for Mercury 41½°, nil; for Venus 262°, (Śīgh-

rocca + 182⁰); for Saturn 152⁰, (Śīghrocca – 88°); for Jupiter 72⁰, (Śīghrocca – 88⁰); for Mars $21\frac{1}{2}$⁰, (Śīghrocca—$88\frac{1}{2}$°). Deduct each type of Ascending Node from the Mean planet and compute the two latitudes for each planet. If they are of the same direction add them. If they are of different directions, subtract one from the other and take the direction of the greater. This is the latitude of the planet.

Note. The *Bhāṣya* and *Sid. Dīpikā* have been followed in this interpretation. It may be seen that with this interpretation the Maximum latitude is not specially given for the Ārdharātrika system, and so it is the same as for the Audayika system. But I think the correct Ascending Nodes and Maximum latitudes according to this system are as follows: Mercury 40°; Venus 260⁰, (Śīghrocca + 180⁰); Saturn 150°, (Śīghrocca — 90°); Jupiter 70⁰, (Śīghrocca — 90°); Mars 20⁰, (Śīghrocca — 90°). The Maximum latitudes of the respective planets are: $1\frac{1}{2}$⁰, 2°, 2°, 2°, $1\frac{1}{2}$⁰, pertaining to both Ascending Nodes.

34. In computing the **True Star-planets (Sphuta graha)**, in all cases, without exception, the procedure is: (i) Half the first Śīghra-phala is deducted from the Mandocca if the Śīghra-kendra is within 6 rāśis and added otherwise. (ii) Half the second Manda-phala is added to the first Corrected Mandocca if the Manda-kendra is within 6 rāśis and subtracted otherwise. (iii) The whole Manda-phala of the third work is subtracted from the Mean planet if the Manda-kendra is within 6 rāśis, and added otherwise. (iv) The fourth work is the same.

35. **The Circumference of the Celestial sphere** is the Moon's cycles (*i.e.* 5,77,53,336) multiplied by 3,24,000 yojanas. This divided by the cycles of each gives the circumference of the orbit of each planet.

CHAPTER VIII

A method to compute the *Tithi* without the Sun or the Moon being found out, is given in 1–4. 5 gives the method to find the Mean Sun from the True Sun. 6 instructs how the arc is to be found from the sine. 7-23 are devoted to various types of examples. Verses 24-25 conclude the work.

1-4. A Method to compute the Tithi without the Sun or the Moon being calculated. (i) Multiply the Ahargaṇa by the Lunar years

(44,52,778) and divide by the days in the Yuga (1,57,79,17,500). Lunar years etc. will be got. (ii) Multiply the Ahargaṇa by the Intercalary lunar years (*viz.* 132,778) and divide by the Yuga days. (iii) Deduct (ii) from (i). The remainders are Mean Solar years, months etc. Omit the years. (iv) From (iii) deduct 2 months, 18 days. The remainder taken as rāśi etc. is the Sun's Anomaly. Using this find the Equation of the Centre (in minutes). Divide this by 12 and add the resulting nāḍis to (i) if the Anamoly is less than 6 rāśis, otherwise subtract. (v) (Multiply the days etc. of (i) by 12 and converting the result into months etc. add the months etc. of (iii). The result are rāśis etc. of the Moon). Find the Equation of the Centre of the Moon (as best you can), divide by 12 and subtract or add the resulting nāḍis in (i) according as the Moon's Anomaly is less or greater than 6 rāśis. (vi) Find the increase in Tithi for the day in minutes (as best you can) and divide by 12. (vii) Multiply the nāḍis etc. of (v) by 60 and divide by (vi). The nāḍis etc. gone after the beginning of the current Tithi is got. (The days give the Tithis gone).

5. **The Mean Sun from the True Sun.** Take the True Sun found by the shadow (in ch. III). Deduct the Higher Apsis and take this as Anomaly. Get the Equation of the Centre. Add this to the True Sun if the Anomaly is less than 6 rāśis, subtract otherwise. The Mean Sun is got. Using this Mean Sun, find the Equation of the Centre again, and add or subtract from the True Sun. A more correct Mean Sun will be got. This may be repeated if necessary.

6. **Arc from the Sine.** (i) From the sine take away as many sine-intervals as possible. (ii) Multiply the number of intervals taken by 225. The result are minutes. (iii) Multiply the remainder of (i) by 225 and divide by the next interval. The result are minutes. Add (ii) and (iii). This is the arc for the sine.

7–9. Three problems on finding the **True Sun from the Noon-day shadow** are given.

10-12. Three problems are given on finding the **True Sun from the E-W Shadow**, i.e. the shadow when the Sun is on the Prime Vertical.

13-22. Various types of problems involving **Kuttakara** (Diophantine equations) already dealt with in the *Bhāṣya* in I. 41-52 are given.

23. A problem is given to find the latitude of the place when the Sun and the duration of the night are given.

24. The author gives his name as Bhāskara, the name of the work, as *Karmanibandha*, and its source, as the Āryabhaṭīya.

25. Conclusion.

* Dr. H. Kern's edition of the Āryabhaṭīya gives the reading, "मध्याह्नात् क्रमगुणितो" and Parameśvara's Vyākhyā in the same edition

also gives क्रम, and not उत्क्रम। But Parameśvara in his Vyākhyā on Govindasvāmin's Bhāṣya edited here, specifically gives उत्क्रमज्या। (cf. V. 42 and V. 45). So it is likely that Govindasvāmin's reading given here is the original reading and Kern's is a corrected reading (corrected for the sake of accuracy). Govindasvāmin's Bhāṣya, Bhāskara's text, (V. 42, 45) and Parameśvara's Vyākhyā thereon, all give only उत्क्रमज्या. Many astronomers before the time of the later Bhāskarācārya (II) seem to have used only उत्क्रमज्या in Valana and not क्रमज्या. For example Lalla, who is reputed to be a student of Āryabhaṭa says—

स्पर्शादिकालजनितोत्क्रमशिञ्जिनीभिः क्षुण्णाऽक्षभा पलभवश्रवणेन भक्ता।
चापानि पूर्वनतपश्चिमयोः फलानि सौम्येतराणि समवेहि पृथक् क्रमेण॥

ग्राह्यात् सराशित्रितयाङ्कजज्या व्यस्ता ततः प्राग्वदपक्रमज्या।
तस्या धनुः सत्रिगृहेन्दुदिक् स्यात् क्षेपो विपातस्य विधोर्दिशि स्यात्॥

But the later Bhāskaracārya (II) says—

खाङ्काहतं स्वद्युदलेन भक्तं स्पर्शादिकालोत्थनतं लवाः स्युः।
तेषां क्रमज्या पलशिञ्जिनीघ्नी भक्ता द्युमौर्व्या यदवाप्तचापम्॥

प्रजायते प्रागपरे नते क्रमाद् उदग्यमाशं वलनं पलोद्भवम्।
युतायनांशोडुपकोटिशिञ्जिनी जिनांशमौर्व्या गुणिता विभाजिता॥
द्युजीवया लब्धफलस्य कार्मुकं भवेच्छशाङ्कायनदिक्कमायनम्।

APPENDIX IV

GLOSSARY OF ASTRONOMICAL TERMS

अक्ष Terrestrial latitude.

अक्षज्या Sine Terrestrial latitude.

अक्षदृक्कर्म Reduction for observation due to the latitude of the observer.

अक्षवलन Bending or change of direction due to the latitude of the observer.

अग्रा 1. Sine Amplitude. 2. The North-South distance of the rising point from the East-West line.

अतिवक्र Maximum retrograde.

अधिदिन Thirtieth part of an intercalary month.

अधिमास Intercalary month.

अधिवर्ष A period of twelve intercalary months.

अन्त्यफल The maximum Equation of the Centre or of Conjunction.

अयन The northward or southward course of the Sun, Moon etc.

अयनदृक्कर्म Reduction for observation due to position on the Ecliptic.

अयनवलन Bending or change of direction due to position on the Ecliptic.

अर्काग्रा Sine Amplitude of the Sun.

अवम Omitted lunar days; also called Tithikṣaya.

अविशिष्ट Successively approximated.

अविशेष Successive approximation.

असित Non-illuminated part of the Moon.

अस्त 1. Setting. 2. Heliacal setting.

अस्तलग्न 1. Setting Sign. 2. Setting or Occident ecliptic point.

अहर्गण Days from epoch. In the present work the epoch is the commencement of Kaliyuga.

आकाशकक्ष्या The great circle forming the projection of the ecliptic on the Celestial sphere.

आक्षदृक्कर्म Same as Akṣa-dṛkkarma.

आक्षवलन Same as Akṣa-valana.

आयनदृक्कर्म Same as Ayana-dṛkkarma.

आक्षवलन Same as Ayana-vaiana.

उच्च Higher apsis, especially pertaining to the epicycle of the Equation of the centre.

उत्क्रमज्या The sum of the Sine segments in the reverse order; *i.e.* if Krama-jyā is sine, the Utkrama-jyā is versine; and if Krama-jyā is cosine, the Utkrama-jyā is coversine.

उदय 1. Rising. 2. Heliacal rising.

उदयज्या Sine Amplitude of the Rising ecliptic point.

उदयलग्न 1. Rising Sign. 2. Rising or Orient ecliptic point.

उद्दिष्ट, उद्देश, उद्देशक Example.

कक्ष्या Orbit.

कक्ष्याकर्ण Radius of orbit.

करण Half-Tithi period, eleven in number, *Śakuni* etc., 4, and *Bava* etc., 7.

कर्ण 1. Hypotenuse. 2. Radius vector. 3. Radius (of orbit).

कालभाग Degrees of time.

कुट्टक, कुट्टाकार Indeterminate equation, also called Diophantine equation.

केन्द्र 1. Anomaly. 2. Centre (of circle).

कोटि, कोटी 1. Perpendicular. 2. Of an angle θ lying between 0° and 360°, the degrees of θ gone in the even quadrants, and to go in the odd quadrants.

कोटिज्या Sine Koṭi, *i.e.* cos θ.

क्रमज्या The sum of the Sine segments taken in the given order.

क्षेप Additive constant, especially that in Kuṭṭaka (Diophantine equation); see also Śeṣa.

खमध्य 1. Meridian. 2. Zenith.

गुणकार 1. Multiplier. 2. The set of solutions in Kuṭṭaka corresponding to the independent variable.

ग्रह Planet, including the Sun and the Moon, sometimes even Ucca and Pāta (the Higher Apsis and the Ascending Node).

ग्रहकक्ष्या The planet's orbit.

ग्रहण 1. Eclipse. 2. Occultation.

चर Declinational Ascensional difference.

चरखण्ड Segment of Declinational ascensional difference.

चरज्या Sine of Declinational ascensional difference.

छाया 1. Shadow of the 12-inch gnomon. 2. Shadow of the Earth. 3. Some-times used as short for Mahācchāyā, *i.e.* Sin Zenith distance.

छेद्यक Graphical representation.

ज्या Sine.

ज्याखण्ड Sine segment or Sine difference.

ताराग्रह "Star-planet", *i.e.* Mercury, Venus, Mars, Jupiter and Saturn.

तिथि Lunar day, *i.e.* 30th part of the lunar (synodic) month.

त्रिज्या The radius of length 3438 units, with the length of a minute of arc taken as unit, and corresponding in the Tabular sines to unity.

दशज्या "The Ten Sines", Bhujājyā, Krāntijyā, Dyujyā, Kṣitijyā, Carajyā, Udayajyā, Madhyajyā, Dṛkkṣepajyā, Dṛgjyā, and Dṛggatijyā.

दिनप Lord of the week-day.

दृक्क्षेप Zenith-distance of the Nonagesimal.

दृक्क्षेपज्या Sine Zenith-distance of the Nonagesimal.

दृग्गतिज्या The square root of the square of Dṛgjyā minus the square of Dṛkkṣepajyā, *i.e.* $\sqrt{\text{Dṛgjyā}^2-\text{Dṛkkṣepajyā}^2}$. This connotation of the term is to be distinguished from the usage of this term in the *Sūrya Siddhānta* where it represents Cos Zenith-distance of the Nonagesimal.

दृग्ज्या Sine Zenith-distance.

दृढ "Reduced", (*i.e.* converted into primes of each other) in Indeterminate Equations.

देशान्तर 1. Difference in Terrestrial longitude. 2. Correction for Terrestrial longitude.

धनु Arc.

नक्षत्र 1. Star. 2. Star-group. 3. Asterismal segment.

नतनाडी Interval in nāḍīs between midday and the time taken.

नतभाग Hour angle; Nata-nāḍī converted into degrees at 6° per nāḍī.

नति Parallax in latitude.

नतिज्या The North-South component of the Great-shadow (Mahā-chhāyā) or Shadow.

नाडिका, नाडी A measure of time equal to one-sixtieth of a day, *i.e.* 24 minutes.

नीचोच्चवृत्त Epicycle.

नीचोच्चवृत्तभङ्गि Epicyclic method.

पद Quadrant.

परिधि 1. Circumference. 2. (The circumference) of the Epicycle.

पर्यय Cycle.

पलज्या Sine latitude.

पलभा Equinoctial shadow.

पात Node, especially the Ascending node.

प्रतिवृत्त Ex-centric circle.

प्रतिवृत्तभङ्गि Ex-centric method.

प्रथमपात Ascending node.

प्राण A measure of time equal to one-sixth of a vināḍī, *i.e.* 4 seconds.

भगण 1. Cycle. 2. 12 Rāśis.

भाज्य Dividend; technically the dividend in Kuṭṭaka or Indeterminate equation.

भुज, भुजा 1. Base. 2. Of the angle θ, lying between 0° and 360°, the degrees of θ gone in the odd quadrants and to go in the even quadrants.

भुजज्या, भुजाज्या Sine Bhujā, *i.e.* Sine of the angle θ.

भूदिन Civil day ; also called Sāvana-dina.

मति Guessed solution in Kuṭṭaka, corresponding to Guṇakāra.

मध्यज्या Sine Meridian Zenith-distance.

मध्यलग्न Sine Meridian Ecliptic point.

मन्द, मन्दोच्च Higher apsis of the epicycle related to the Equation of the centre.

मन्दकर्ण Radius vector.

मन्दपरिधि The Epicycle of the Equation of the centre.

महाच्छाया Great-shadow, *i.e.* Sine Zenith-distance.

महाशङ्कु Great-gnomon, *i.e.* Sine Altitude.

मोक्ष Last contact (in an eclipse).

याम A period of time equal to one-eighth of a day, *i.e.* 3 hours.

योग (In this work) name of the astronomical phenomena, Vyatīpāta, Vaidhṛta and Sārpamastaka.

योगतारा Junction-star.

योजन A measure of distance equal (in this work) to about $7\frac{1}{2}$ miles. According to the *Sūrya Siddhānta* and the *Siddhānta Śiromaṇi* it corresponds to about 5 miles.

योजनव्यास Diameter in yojanas.

राहु 1. Node of the moon, especially the Ascending node. 2. The earth's shadow.

लग्न Ecliptic point on the horizon; commonly the Rising point of the ecliptic.

लङ्कोदय Right Ascensional difference.

लङ्कोदयराशिमान Segments of Right Ascensional difference, corresponding to the Rising of the Signs.

लब्ध 1. Result or quotient. 2. The set of solutions in Kuṭṭaka corresponding to the dependent variable. 3. Also the corresponding guessed solution in Kuṭṭaka.

लम्बज्या Sine Co-latitude, *i.e.* Cos (Terrestrial) latitude.

लम्बन Parallax in latitude, in terms of time.

लिप्ताव्यास Angular diameter in minutes.

वक्र Retrograde.

वर्षप The Lord of the year.

वलन Bending, change of direction.

विक्षेप Celestial latitude, *i.e.* latitude of planet or Moon.

विनाडिका, विनाडी Measure of time equal to one-sixtieth of a nāḍī; 24 seconds.

विमर्दार्ध Half total obscuration (in an eclipse).

विषुवच्छा Equinoctial shadow, *i.e.* the midday shadow of the 12-inch gnomon when the sun is at the Equinox.

विष्कम्भ Diameter.

वैधृत One of the yogas; the time when Sun plus Moon equals 360°, *i.e.* 12 Rāśis.

व्यतीपात One of the yogas; the time when Sun plus Moon equals 180°, *i.e.* 6 Rāśis.

व्यास Diameter.

शङ्कु 1. Gnomon. 2. 12-inch gnomon. 3. Sometimes shortened form for the Great-gnomon (Mahā-śaṅku, Sine Altitude).

शङ्क्वग्र The north-south distance of the rising or setting point, from the tip of the shadow, *i.e.* Agrā ± Natijyā.

शीघ्र, शीघ्रोच्च The Higher apsis of the epicycle of the Equation of conjunction.

शीघ्रकर्ण Geocentric Radius vector.

शीघ्रपरिधि The Epicycle of the Equation of conjunction.

शृङ्गोन्नति The elevation of the horn of the Moon.

शेष The subtractive constant in Kuṭṭaka. See also Kṣepa.

सममण्डल The Prime vertical.

समशङ्कु Sine Altitude of the Sun on the Prime vertical.

सार्पमस्तक One of the yogas; the time when Sun plus Moon is equal to 7 Rāśis 16° 40′.

सावनदिन Civil day; also called Bhūdina.

सित The illuminated part of the Moon.

सौरदिन Solar day; the period which the sun takes to move one degree; one-thirtieth of a Solar month.

सौरमास Solar month; the period which the Sun takes to move 30 degrees; one twelfth of a Solar year.

सौरवर्ष Solar year; the period of one cycle of the Sun.

स्थित्यर्ध Half-duration of the eclipse.

स्पर्श First contact (in an eclipse).

स्फुट True position (of a planet); Making the (Mean) position true.

स्वदेशराशिमान Segment of Oblique Ascensional difference corresponding to a Rāśi.

हार Divisor, technically the divisor in Kuṭṭaka.
